18 Running title: outbreak of CDI caused by ribotype 826

19

20 Keywords: Clostridium difficile, epidemiology, outbreaks, infection control, surveillance

21	Abstract
22	<b>Objectives.</b> The aim was to investigate an unusual outbreak of 5 patients with in total 8 episodes of a
23	Clostridium difficile infection (CDI) on a gastro intestinal surgical ward of a Dutch tertiary care
24	university affiliated hospital.
25	Methods. Clinical case investigations and laboratory analyses were performed. Laboratory analyses
26	included PCR ribotyping, MLVA typing, toxinotyping, antimicrobial susceptibility testing and whole
27	genome sequencing.
28	<b>Results.</b> The outbreak was associated with recurrent and severe disease in 2 out of 5 patients. All
29	episodes were due to a unique ribotype that was not recognized in the collection of an international
30	network of reference laboratories and was assigned PCR ribotype 826. PCR ribotype 826 is a toxin A,
31	toxin B and binary toxin positive ribotype which according to molecular typing belongs to clade 5
32	and resembles the so called "hypervirulent " ribotype 078. The presence of a clonal outbreak was
33	confirmed by whole genome sequencing, yet the source of this newly identified ribotype remained
34	unclear.
35	<b>Conclusion.</b> This newly identified <i>C. difficile</i> PCR ribotype 826 is part of clade 5 and might as well
36	have increased virulence. The recognition of this outbreak highlights the need of ongoing CDI
37	surveillance to monitor new circulating ribotypes with assumed increased virulence.

## Introduction

We identified an outbreak of eight episodes of CDI in five patients within a 4-month period (1

December 2015-31 March 2016). The outbreak occurred on a gastro-intestinal surgical ward of a

Dutch tertiary care hospital. In this case series, we describe the clinical characteristics of affected

patients and microbiological investigations that were performed on the identified strain.

#### Methods

The case series was conducted at a gastro-intestinal surgical ward of the Erasmus University Medical Center in Rotterdam, the Netherlands. The Erasmus MC participates in the national sentinel CDI surveillance program and therefore sends all samples from hospitalized CDI patients to the national Reference Laboratory for PCR ribotyping (1, 2). In case of an outbreak (defined as >2 isolates of the same type detected less than 7 days apart in one hospital either with onset of symptoms on the same ward, or accompanied by an increased CDI monthly incidence within the hospital (3)) additional analyses can be performed by the Reference Laboratory. These include multiple-locus variable-number tandem-repeat analysis (4), PCRs for toxin genes (5), PCRs for clade specific makers (6), antimicrobial susceptibility screening tests (E-test) and whole genome sequencing (7). Patient information and medical history from all CDI cases during this outbreak were collected from the electronical medical records. Defined daily doses for all antibiotics used up to three months before development of CDI and Charlson co-morbidity scores were calculated. (8). CDI was classified as severe if one or more of the following conditions were present (attributable to CDI): fever (equal or above 38.5°C), rigors, hemodynamic instability, ileus, peritonitis, mental status changes, admission to ICU, end organ failure, leukocytosis (>15 x 10<sup>9</sup>), leukopenia (<2 x 10<sup>9</sup>), hypoalbuminemia (<30g/L), >1.5-fold increase in creatinine level above baseline, serum lactate >2.2mmol/L, pseudomembranous colitis, colonic wall thickening, pericolonic fat stranding or ascites. All other cases were classified as mild CDI. (9, 10).

69	Written approval to conduct the case series was received from the medical ethics research
70	committee of the Erasmus MC Rotterdam, the Netherlands (MEC-2015-306).

71

#### **Results**

72 73 The CDI incidence rate on the gastro-intestinal surgical ward was 3.3 per 10,000 patient days (July 74 2009-November 2015) and increased to 19.8 per 10,000 patient days (December 2015-March 2016). 75 In total, 6 patients with CDI were diagnosed of which 5 had the same PCR ribotype. 76 The index case A of this outbreak was an 83-year old male patient who underwent a 77 pancreaticoduodenectomy because of a carcinoma of the common bile duct one month earlier. In 78 December 2015, during a readmission because of infected ascites, he developed diarrheal symptoms 79 and was diagnosed with hospital-acquired CDI. Within one week after the start of his symptoms, two 80 other patients (B and C) on the same ward were diagnosed with hospital-acquired CDI. All three 81 patients were treated with a 7-11 day oral course of metronidazole and discharged. 82 In January 2016, a fourth hospital-acquired CDI case (D) on the ward was noticed. In February 2016, 83 84 case A was readmitted because of a CDI recurrence and a fifth case (E) was reported. Case A was readmitted once more due to a second recurrence in February and case D was also diagnosed with a 85 CDI recurrence in March. In total, 4 out of 8 CDI episodes (in 2 patients) were classified as severe 86 87 CDI. None of the patients were admitted to the ICU due to CDI, and no CDI-related mortality (within 88 30 days) occurred. All patients had used antibiotics before acquiring CDI and total defined daily 89 doses of antibiotics used before onset of CDI ranged from 21 to 63 (median 26.9). Four out of 5 90 patients had used proton pump inhibitors before the CDI diagnosis. The median Charlson co-91 morbidity score was 2, ranging from 0 to 8. 92 In accordance with local guidelines, all patients suspected of or having CDI were placed in a single 93 room and were not allowed to use shared sanitation. Medical personnel wore protective disposable 94 gowns and gloves when entering the room and handwashing with soap and water was endorsed.

Isolation precautions were discontinued 48hours after resolution of diarrheal symptoms. In reaction to this CDI outbreak, additional infection prevention measures were implemented on the ward during certain time periods (see Figure 1). These additional infection prevention measures included cleaning and disinfection using 1000ppm chlorine of the following items: automatic bedpan washer (daily), toilet chairs (after each use), utility room and sanitation (daily or twice daily) and all patients rooms of half the department (once, after recognition of the fifth case). Additionally, the metal bedpans were replaced by cardboard single use bedpans. Moreover, after the fifth case was diagnosed, 56 environmental swabs were taken on 2 different sampling days: February 19<sup>th</sup> and February 24<sup>th</sup>. Samples were taken from: sink, water tap, grip of cabinet, alarm system, dustbin, chairs/tables and bed curtains of a room that had been occupied by a CDI patient (before final cleaning); the same items in a clean room (after cleaning and disinfection with 1000pppm); and toilet, shower chair, sink, shower curtain, sack of laundry and towel dispenser of a shared bathroom (after cleaning and disinfection). Environmental swabs were inoculated in C. difficile enrichment modified broth (Clostridium difficile enrichment broth, Mediaproducts BV, Groningen, The Netherlands) for 1 week and subcultured on CLO plates (Clostridium difficile agar, Biomerieux, Marcy l'Etoile, France). No antibiotic restriction policy was implemented during this outbreak.

Stool samples of all 5 patients tested positive for toxin B and binary toxin genes in the Xpert *C. difficile*; however, the *TcdC*Δ117 deletion specific for ribotype 027 was not identified. Investigations at the Reference Laboratory demonstrated the presence of *TcdA*, and confirmed the presence *TcdB* and the binary toxin genes. In addition, a 39-bp deletion in *TcdC* was detected.

All 5 isolates and one isolate obtained from an environmental culture (taken from the sack of laundry in the shared bathroom after cleaning and disinfection) displayed the same PCR ribotyping profile. The profile was not recognized in the Dutch Reference Library (which is able to recognize 221 different PCR ribotypes) but resembled the profile of ribotypes 078, 126 and 066 most (all belonging to clade 5) (Figure 2a). A dataset of sized fragments obtained by capillary gel-based electrophoresis

PCR ribotyping (2) was sent as FSA-file to international C. difficile reference laboratories (including the Leeds collection encompassing more than 800 PCR ribotypes, the WEBRIBO system, the CDC database and databases from Sweden, Portugal, Belgium, and Canada), but no match was found. The new strain was assigned as ribotype 826 by the Leeds Ribotyping reference network. PCR analysis of a clade 5 specific DNA marker (6) revealed that all ribotype 826 isolates were positive for the marker, confirming that ribotype 826 is part of clade 5. According to Clinical and Laboratory Standards Institute (CLSI) breakpoints, all isolates were susceptible for erythromycin (MIC<2), clindamycin (MIC<2), metronidazole (MIC=<2) and vancomycin (MIC<2), but resistant to ciprofloxacin (MIC>32) and moxifloxacin (MIC>32)(11). The isolates were 100% identical with 0 summed tandem-repeat differences (STRD), thereby confirming a clonal complex according to MLVA. In addition, whole genome sequencing was performed (Figure 2b). To provide phylogenetic context, reference strains 078, 126/078, 045, 033 and 066 and 4 patient samples from confirmed 078 cases were included. In total, 1678 SNPs were identified within this sample selection which is the expected variation between different ribotypes of one clade. Within the outbreak isolates, only 2 SNPs were identified (there was 1 SNP difference between the isolate from the recurrence in case A compared to the initial case A isolate and 1 SNP difference between the case D /case E isolates and the initial case A isolate). Clonality of these cluster isolates was thus confirmed by whole genome sequencing as the commonly used cut-off for classifying isolates as clonal is 0-2 SNPs (7).

#### Discussion

The occurrence of this CDI outbreak was uncommon as it occurred on a ward where transmission of *C. difficile* was rare, as proven by sentinel CDI surveillance. Also, two out of five patients had recurrent disease and were severely affected. Cases were due to a newly identified ribotype 826.

Additional investigations showed that ribotype 826 belongs to clade 5 with a characteristic clade 5 specific DNA marker and a 39bp deletion in *TcdC*. Whole genome sequencing revealed that ribotype

826 resembles the ribotype 078 quite well. CDI cases due to clade 5 ribotypes have been reported to be associated with the highest 14-day mortality (12). We therefore assume that this new ribotype also has increased virulence, explaining the occurrence of this outbreak.

Whole genome sequencing results demonstrated clonality thereby confirming transmission, but still unanswered questions are what the source of this ribotype was and how transmission occurred. The index patient could have introduced this ribotype into the ward, although no unusual profession, recent travel or other remarkable expositions were reported. Alternatively, an undetected asymptomatic carrier might have introduced the ribotype and spread it to other patients.

Transmission could have occurred via shared items as contamination was demonstrated in one of the environmental cultures, but unfortunately environmental swabs were only taken after the last patient was detected. The outbreak ceased with the implementation of additional infection prevention measures, suggesting that these cleaning and disinfection measures were effective, probably together with a raised awareness among the healthcare workers. Since most PCR ribotypes of clade 5 are also found in animals, it is tempting to speculate that the newly recognised ribotype 826 derives from animals. The lack of this PCR ribotype in the databases of human collections supports this hypothesis. Unfortunately, reference laboratories for animal associated *C. difficile* infections are not available that could be used to match our isolates. To the best of our knowledge, no additional 826 isolates have been detected since this outbreak.

This outbreak indicates that new *C. difficile* ribotypes with increased virulence still emerge, at unexpected locations and without a clear source. Given the increased virulence and still unknown source of this newly identified ribotype, ongoing CDI surveillance remains essential and other institutions should now be aware of ribotype 826.
