Abstract

Although energy is a concept that is implied in many motivational theories, is hardly ever explicitly mentioned or researched. The current article first relates theories and research findings that were thus far not explicitly related to energy. We describe theories such as flow, subjective well-being, engagement and burn-out, and make the link with energy more explicit. Also, we make a first link between personality characteristics and energy, and describe the role of leadership in unleashing followers’ energy. Following, we identify how the topic of energy management can be profitably incorporated in research from a scientific as well as a practitioner viewpoint. Finally, we describe several interventions to enhance energy in individuals and organizations.

Keywords: Energy; review; intervention; time management; positive psychology; leadership
Energy Management of People in Organizations: A Review and Research Agenda

“In organizations real power and energy is generated through relationships. The patterns of relationships and the capacities to form them are more important than tasks, functions, roles and positions” -- Margaret Wheatley

Energetic employees are imperative for an organization’s success. People with a lot of energy are more productive, creative and they have a positive influence on others (Ash, 1913; Cross, Baker, & Parker, 2003; Cross & Parker, 2004). When there is a high energy level within an organization, everything seems to happen more easily. Employees stimulate each other by continuously giving that extra bit of effort, and of course, this is also positive for the organization (cf. Bruch & Ghoshal, 2003; Cross & Parker, 2004). Although in Eastern philosophy “Qi” (life power or energy flow) is a pervading concept that is often mentioned in relation to physical and mental health and fitness, in Western philosophy and theory it remains more implicit. Although early psychologists (e.g., Freud) and sociologists (e.g., Ash) mentioned human energy in relation to mental and physical health, later theories hardly ever mentioned nor measured energy explicitly. Since the beginning of this century, this is starting to change and more attention is being paid to positive psychology (Seligman & Csikszentmihalyi, 2000), the study of positive social interactions for optimal human functioning (e.g., Heaphy & Dutton, 2008). Many motivational constructs do imply energy, but still hardly ever explicitly mentioned it. Only few studies have directly measured energy and its effects (e.g., Bruch & Ghoshal, 2003; Cross et al., 2003; Ryan and Frederick, 1997).

Thus although in the management and psychology literature, many theories seem to have a more or less energetic implications, most theories do not explicitly mention energy levels as part of the theory. Theory and research regarding burnout (e.g., Maslach & Schaufeli, 1993) can
be seen as concerning a lack of energy, more specifically exhaustion at the physical, emotional and cognitive level, due to being exposed to stressors for a prolonged period of time (for a review see Maslach, Schaufeli, & Leiter, 2001). Even in those theories, energy is often not explicitly mentioned, but the lack of energy is referred to as “emotional depletion”. A lack of energy is also discussed in theory and research regarding emotional dissonance (i.e. the conflict between inner real feelings and required or shown feelings; (Middleton, 1989), and emotional labor Brotheridge and Lee, 2003; Grandey, 2003; Morris and Feldman, 1996). In jobs with a lot of emotional dissonance, requiring emotional labor, energy may be drained quickly and may even lead to a downward spiral of energy loss (van Gelderen, Heuven, van Veldhoven, Zeelenberg, & Croon, 2007), or even burnout (Bakker & Heuven, 2006).

Examples of theories describing energy gains more explicitly are engagement, or a positive work-related state, characterized by vigor, dedication and absorption (Gonzalez-Roma, Schaufeli, Bakker, & Lloret, 2006) Schaufeli, Salanova, González-Romá, & Bakker, 2002), and the somewhat less well-known theories of thriving, or “the psychological state in which individuals experience both a sense of vitality and a sense of learning at work” (Spreitzer, Sutcliffe, Dutton, Sonenshein, & Grant, 2005), p. 538), and human flourishing (Fredrickson & Losada, 2005).

In the current paper, we will first define energy, describe the literature in this emerging field, and discuss concepts that have an energetic connotation, such as “flow” (Csikszentmihalyi, 1990; Csikszentmihalyi & LeFevre, 1989), “engagement & burn-out” (Gonzalez-Roma et al., 2006; Schaufeli, Bakker, & Salanova, 2006), “emotional dissonance” (Morris & Feldman, 1996), “thriving and flourishing” (Fredrickson & Losada, 2005; Spreitzer et al., 2005), “time management” (Adams & Jex, 1999; Macan, 1994), “work recovery” (Sonnentag, 2003), and
“conservation of resources” (Hobfoll, 1989). Next, we will describe an energy enhancing intervention. Throughout, an important goal of the paper is to offer a research agenda next to the review of the literature.

Definition of energy

Energy can be defined as ” a type of positive affective arousal, which people can experience as emotion — short responses to specific events — or mood — longer-lasting affective states that need not be a response to a specific event” (Quinn & Dutton, 2005, p. 36). Energy can be both a short-term and a long-term process. Just like for instance satisfaction, people can experience long-term (basic energy level) as well as short-term effects on their energy level. Long term draining effects can result in a burnout, and should probably be viewed as deviations of a persons’ basic energy level. Research regarding flow defined as “the way people describe their state of mind when consciousness is harmoniously ordered, and they want to pursue whatever they are doing for its own sake” (Csikszentmihalyi, 1990, p. 6), shows that people can be completely focused and energetic in all domains, be it sports, games, hobbies or work. This complete immersion in an activity is the result of the focusing of mental energy on an activity which is liked by the actor. Flow is a source of mental energy, in that it focuses attention and motivates action. However, an important reason why people often lack energy is that they have trouble determining what they really like and even if they know what activities they like best, fail to seek out these activities more often. In order to become more energetic Csikszentmihalyi, 1997 (p. 127) advises:

“We must then transfer some psychic energy each day from tasks that we don't like doing, or from passive leisure, into something we never did before, or something we enjoy doing but don't do often enough because it seems too much trouble.”
Energy level. Practitioners often deal with workers who are seeking to maintain an optimal energy level, despite the stressors they have to deal with on a daily basis. Energy can be seen as a valued resource, that people strive to retain, protect and/or gain (Hobfoll, 1989). Three kinds of energy are often discerned, namely (a) mental energy (being able to intensely focus), (b) physical energy (strength, endurance, flexibility), and (c) emotional energy (being in touch with one’s own feelings and core values). These are similar to, but seemingly the antipodes of the dimensions of burnout (Maslach et al., 2001). Within the energy dimensions, three characteristics of energy can be discerned, namely the amount, stability and direction of the energy.

For instance, when a person has a high amount of mental energy, but stability and direction are low, then this person can focus intensely on a task, but only for a short period of time and without much direction, and often this will not lead to great results. However, if a person has a clear direction of energy, and is aware of the low stability, this can be dealt with by short bouts of intense focused actions. However, having to “keep up appearances” at work, creating a façade of conformity, while ones personal values differ, may be a drain in terms of emotional energy (Hewlin, 2003).

Extensive experience in energy management training sessions of the second author show that having a lot of physical energy is no guarantee of success when the stability of energy is not in order. No matter the amount of energy, without direction of energy, problems will occur, as the energy is not linked to targets, but to random actions without higher target or link to the mission. This is also mentioned by Cross and Parker (2004), where they discuss the role of “energizers” in their research, opposing them to “de-energizers”. Energizers are trustworthy people in the organization (not necessarily managers), that have a compelling vision and are able to convince others around them to work towards this mission. De-energizers are the black holes
in an organization, draining the energy of their co-workers and leaders. This may have to do with personality characteristics of the person (e.g., Burke & Witt, 2004), or their specific behavior. According to Cross et al. (2003, see also Cross and Parker, 2004), especially political behaviors can be extremely draining. Network analyses by Cross et al. (2003) showed that energizers and de-energizers can have a powerful influence on the performance of people around them (see also Leiter and Maslach, 1988). People experiencing a burnout can also negatively influence the energy of other in the workplace (Maslach et al., 2001).

How then can we make sure to be energized and energize others? What are the factors that play a role in energizing? In the next sections we will describe personal characteristics and behaviors that discern energizers from de-energizers.

**Personality, behavior and leadership styles**

What discerns people and managers high on energy from people low on energy? Are people high on energy better in touch with their feelings, and hence make the right choices? Are they better in prioritizing and do they therefore have more energy? Or is it just because people high on energy do the things they like, and are good at, so that work does not feel like work? Energetic people achieve their goals sooner, and enjoy the road to these goals better. Indeed better person-job fit has been related to a higher level of engagement and less burn-out (Chilton, Hardgrave, & Armstrong, 2005; for a review see Maslach et al., 2001). Also, having a clear goal is a prerequisite to the focusing of energy (Csikszentmihalyi, 1997). At the same time, the behavior of energetic people can be contagious for the productivity of others in their immediate surroundings (Bakker, Demerouti, & Schaufeli, 2005).

Although some questions are answered relating to recovery and work-life balance (e.g., Sonnentag, 2001, 2003), many questions relating to how we can get less drained during work
hours are still not answered. The extent to which people cope with stressors, or let energy drains rule their lives is an important variable in maintaining energy, and the relationships surrounding these is an important research question (Cross et al., 2003; Cross & Parker, 2004). In this respect, the notion of energy enhancers, people that energize others around them, may be an interesting starting point. How is energy spread through a network? At the same time the concept of energy enhancers may have some overlap with the concept of subjective well-being (Diener, 1984), as people high on subjective well-being may also be high on energy. Research has indeed shown a positive relationship between vitality and well-being (Ryan & Frederick, 1997). At the same time, being high on energy may be distinct from energizing others, although being high on energy yourself may be a requirement.

Organizational energy often starts with the energy of a few key figures (Bruch & Ghoshal, 2003). Transformational leaders are traditionally considered as energizing: the idea is that those leaders are able to inspire others and change the way people work toward a common goal (cf. Bass, 1985; Kark & Van Dijk, 2007; Yukl, 1998). For instance, research among 32 teams from various kinds of industries has shown that teams with a transformational leader are more likely to have a shared vision, which in turn relates to more team reflexivity (i.e. the process of reflecting on and adapting of goals, strategies and processes) in turn enhancing team performance (Schippers, Den Hartog, Koopman, & van Knippenberg, 2008). The behavioral component underlying the success of transformational leadership may be regulatory focus theory (Higgins, 1998; Kark & Van Dijk, 2007). Within this theory, two motivational orientations are discerned, promotion focus, referring to a more “risky” information processing style, while prevention focus is related to a more risk-averse and vigilant processing style (Higgins, 1998). Promotion goals refer to ideals, hope and aspirations, while prevention goals refer to duties, responsibilities
and things that ought to be done (Kark & Van Dijk, 2007). People with a promotion focus are more creative problem-solvers (Friedman & Förster, 2001), are more willing to take risks, and may be better able to energize people around them towards compelling goals (c.f. Brockner & Higgins, 2001; Crowe & Higgins, 1997). Promotion focus seems a more energetic style (i.e. vision, hope), while prevention focus may be related to a de-energizing style (i.e. always seeing roadblocks and reasons why projects will fail). A transformational leadership style may very well be related to a promotion focus, while a transactional leadership style may be more related to a prevention focus, and hence transformational leaders may be better able to energize followers into action toward a common goal (Kark & Van Dijk, 2007). The effects of transformational leadership may thus be mediated by the energy they create towards this common goal. Research has shown that the success of a promotion or prevention appeal is dependent on the fit between leaders and followers regulatory focus (Stam, Knippenberg, & Wisse, 2010). Although we do not know of any research explicitly investigating the role of promotion versus prevention focus in enhancing or diminishing energy level, people with a promotion focus may be more goal oriented (e.g. possible gains) and less distracted by thoughts of what they ought to do, or ruminating about failure (e.g., possible losses), while people with a prevention focus will be more inclined to ruminate about possible losses and spend time on counterfactual thinking (Roese, Hur, & Pennington, 1999). Consequently, people with a promotion focus will be better able to focus their energy on the goal and be more productive. This may be a viable route for future research to determine the relationship between leadership, regulatory focus, and followers’ energy.

A related personal characteristic may be personal initiative (Frese & Fay, 2001), or proactive behavior (Bateman & Crant, 1993). Persons high on proactive behavior are more
inclined to take charge (Morrison & Phelps, 1999), overcome barriers and deal proactively with demands (Frese & Fay, 2001; Sonnentag, 2003). Proactive behavior has been related to a reflexive style of thinking in teams (Schippers, Den Hartog, & Koopman, 2007). Research has shown that proactive behavior is related to work recovery. A study among 147 employees of six public service organizations showed that recovery after work had a positive effect on work engagement the next day, and in turn taking initiative and pursuing learning goals at work (Sonnentag, 2003). Thus, being able to rest and recover after work is important for energetic behavior in the form of taking initiative and learning during the work day.

A personality variable that may be negatively related to energy at work is neuroticism, or emotional instability. Neurotic individuals may waste a lot of energy, because they are inclined to ruminate excessively (Nolan, Roberts, & Gotlib, 1998; cf. Eisenberger, Lieberman, & Satpute, 2005), especially when they are under stress. Research among 109 out-patients suffering from unipolar depressive disorder has shown that neuroticism is related to dysfunctional ruminating and subsequent depression as reactions to stress (Lam, Smith, Checkley, Rijsdijk, & Sham, 2003). Interestingly, “analyze to understand” was the only rumination subscale not related to depression in their research (Lam et al., 2003). Other research has related neuroticism to fatigue (Calderwood, 2009) and burnout (for a review see Maslach et al., 2001). This research suggests that neurotic individuals may be inclined to waste their energy in dysfunctional ruminating, leading to a lowered energy level, fatigue, and in extreme cases depression.

Other personality characteristics related to energy at work may be agreeableness, conscientiousness and self-esteem. Workers high in conscientiousness are reliable, methodical, disciplined and organized, while workers high on agreeableness are cooperative, helpful and tolerant (Costa & McCrae, 1992). People high on agreeableness and low on self-esteem will have
trouble saying no (cf. Joseph, 2000; Judge & LePine, 2007). If these persons are also high on conscientiousness, they will not only have trouble saying “no” to requests, but will also most likely act on their promise (Costa & McCrae, 1992). When all these requests are being fulfilled, these workers may not have done the things that are important in achieving their own results. Consequently, in the long term, this may result in energy loss and burnout. Research by Ryan and Frederick (1997) indeed found extraversion, conscientiousness and neuroticism to be significantly related to vitality.

Intra-individual combinations of conscientiousness and agreeableness may also explain “high maintenance” -- chronic annoying and de-energizing -- behavior in the workplace (Burke & Witt, 2004). This “high maintenance” behavior tends to exhaust supervisors and co-workers of their morale, energy and time, while at the same time driving high-performing co-workers out of an organization (Grensing-Pophal, 2001; Principe, 1997). Research among 336 clerical workers in a production organization showed that workers with high or low conscientiousness combined with low agreeableness received higher scores on supervisor rated high maintenance behavior. In contrast, workers with a combination of high conscientiousness and high agreeableness received the lowest ratings of high maintenance behavior, and were experienced as least de-energizing (Burke & Witt, 2004). This research suggests that different combinations of personality will result in energizing or de-energizing behavior. Future research could investigate the functional and dysfunctional role of personality with respect to energy. For instance, extraversion and openness to experience have not been explicitly related to energy before. Since the relation between personality and subjective well-being has been extensively researched (for reviews see DeNeve & Cooper, 1998 and Diener, Suh, Lucas, & Smith, 1999), this may be a good starting point for related research regarding personal energy level and energizing behavior.
Relation to career success

Are people high on energy and well-balanced also more successful in their careers (and lives)? If yes, what are those factors that determine this? To our knowledge, there is no scientific evidence showing this relationship. However, research on expert performance showed that long-term success in any discipline is determined by the actual time an individual works at his or her most important goals on a weekly basis, and that it takes ten years of deliberate practice before a person can really excel in a specific discipline (e.g., chess; Ericsson, Krampe, & Tesch-Römer, 1993). Other research has looked at the differences between “superworkers” and moderate performers. For instance, research among forty software designers, comparing “superworkers” (who seem to be able to focus their energy toward important goals), and moderate performers, showed that high performers spent more time on local planning and feedback processing, whereas moderate performance were more engaged in analyzing requirements and verbalizing task-irrelevant cognitions, such as ruminating about possible failure (Sonnentag, 1998). Similar effects have been found for expert performance (for a review see Ericsson and Lehmann, 1996). Experts spend a considerable amount of energy focusing on becoming the best in their discipline, and are highly motivated by their goal. This is so much so, that they economize on social interactions, and as a consequence are often seen as self-centered during their (sports) career (Jones, 2006).

Although not everyone will want to become a top performer, this research is informative in showing how one can stay energized while reaching the goals in work and life. Even when people have a clear goal, it is sometimes hard to stay focused. The question then is: how can a task focus be enhanced? Two things may play a role here: (a) The extent to which a person
reflects on his/her short and long-term goals and (b) the extent to which the person reflects on the consequences of this goal for everyday actions.

**Awareness of energy: Reflection on energy might help refocusing.**

The complaint of modern times is that we do not have time and that we are busy all the time. However, closer inspection of what people really do reveals that most people waste a lot of time instead of doing what they really need or want to do. For instance, research among managers of a global airline company and a large oil company, showed that that fully 90% of them wasted time and productivity, despite having well-defined objectives and goals (Bruch & Ghoshal, 2002). The researchers assert that the reason for this productivity and energy loss (which they dubbed “active non-action”) is a perceived lack of personal discretion or control. Note that these were all managers, who are generally seen as having more freedom in setting their goals and ways to achieve them then subordinates. These managers mistakenly thought they had no choice in cancelling meetings, talking to people, etc., and did not reflect on how to spend their time most effectively. In contrast, successful managers were the ones that did take initiative and acted on opportunities (Bruch & Ghoshal, 2003). Only 10% of the managers in the oil company spent their time in a committed, purposeful and reflective manner (Bruch & Ghoshal, 2002). Those managers were able to focus in a proactive way: having reflected on what their goal was, they did not get sidetracked by all kinds of distractions, such as e-mail, meetings and unforeseen demands. This suggests that workers that reflect on the most efficient use of their time will use their energy better and more effectively than those that don’t.

Indeed, performance improvement in all kinds of domains may be achieved through a process of reflexivity – reflecting upon work processes and performance (Schippers et al., 2007; West, 1996, 2000). For instance, research among 73 student teams showed that teams reflecting
on their performance after detrimental initial performance, were able to improve their final teams performance (Schippers & Homan, 2009). Furthermore, research among teams in hospitals, having much discretion, showed that teams that were more reflexive, were better able to deal with, and reacted more innovatively with respect to the demands of workload and demanding work facilities (Schippers, West, & Dawson, 2010). Together, this research suggests that reflexivity may be important in (a) realizing the real amount of discretion people have, and (b) their ability to change and refocus the situation. This may be energizing in the sense that people will try to actively change the situation, instead of a “learned helplessness” attitude (Abramson, Seligman, & Teasdale, 1978). In a sense, the underlying mechanism in the above findings may be that reflexivity helps in becoming aware of things that can be changed and improved, and a subsequent refocusing of energy towards this (new) goal.

Measurement and Research Agenda

Energy could be measured by asking people what kind of work gives them most satisfaction, how often they perform these tasks, how well they achieve their goals, and how much time they spend on recovery from work, including physical activities. Also, how energetic people feel, and how involved they are during work hours, and how much energy drains they experience at work. We discussed the possible role of leadership in this respect. Recent research regarding leadership suggests that servant leadership, with its’ focus on others instead of the organization (Nuijten, 2009; Stone, Russell, & Patterson, 2004; van Dierendonck & Nuijten, 2010), may also be a viable route for future research in relation to unleashing followers energy. On the basis of the above review, future research could explore (a) what discerns people high on energy from people low on energy? (b) are people high on energy/well-balanced also more successful in their careers (and lives)? and, if yes, (c) what are effective tools that can help, and
(d) how can an intervention be developed to make sure that, in principle, everyone can reach this success (not just the “lucky few” who happened to reach this).

Summarizing, in the above we have raised several questions that future research could help to answer. These include:

- How can energy best be measured?
- Are people high on energy also energizers? Or are these constructs relatively independent? Is being high on energy a prerequisite for being an energizer? What is the role of these energizers in unleashing organizational energy?
- What personality variables are highly related to energy? Is there a combination of personality traits that is most strongly related to energy?
- How does energy flow through networks in organizations?
- Is energy related to subjective well-being?
- What is the role of leadership in unleashing followers’ and organizational energy? How does the combination of transformational or servant leadership and regulatory focus affect followers energy? What is the role of regulatory fit in this respect?

Next to research looking at determinants and outcomes of energy, as was outlined above, the effects of possible interventions should be assessed. As Maslach et al. (2001) noted, limitations in study design, especially the lack of control groups and longitudinal studies limits extent to which research findings regarding the effect of interventions can be interpreted. Future research could incorporate the level of energy both before and after an intervention, and especially the long-term effects of such interventions. Below, we will describe what is known about energy enhancing interventions, and describe what an effective intervention could look like.
Practical tools that help in creating and maintaining energy

Several practical tools could be helpful in preserving energy during the work day. Some questions that research could answer here are: What are the most effective tools that can help in energy management? For instance, does the use of formalized tools such as Outlook, to-do lists, add or detract from workplace stress? Does the practice of “blocking one's calendar out”, so that others cannot put surprise meetings on, work in this respect? Is there a “perfect combination” of tools one can use, and if yes, which one works best?¹

On the basis of the experience of the second author, who is an experienced trainer in energy and time-management, three main practices can be discerned that work well: (1) Planning according to result areas, (2) reflect on long-term goals, and (3) physical fitness.

Planning according to result areas. First, it is important to plan according to result areas (acquisition, finance, innovation) instead of on random actions. This makes planning survey-able and result-oriented. Doing so, the random actions will be prioritized and ordered within the appropriate result-area. For instance, in science two large result areas are teaching and research, which can of course have several result areas as part of these two broad areas, such as different research projects. Successful workers are capable of making important things urgent, and make sure to spend time on these tasks on a daily basis (cf. Ericsson & Lehmann, 1996; Hall & Hursch, 1982). Spending time on important tasks every day is more effective than “blocking one’s calendar out” sometimes, because for most workers these days are rare and do not provide enough time to make progress on important tasks. In the long run, it is much more efficient to do a few big things (e.g., making progress toward the goals within the result areas, than do a lot of

¹ We thank the special issue editor Allan Church for suggesting this research question to us.
small things without a direct measurable consequence towards their main goals (cf. Hall & Hursch, 1982)

Most people get sidetracked by the urgency principle, where deadlines, e-mails and meetings determine their daily actions. Interruptions can be very disruptive for the work flow (Fisher, 1998). Although workers sometimes get something out of interruptions, if they are triggered often to switch to other result areas, they lose energy because of time they need to refocus their attention. Sometimes, they even forget what they were doing and get sidetracked altogether (Fisher, 1998; Mark, Gonzalez, & Harris, 2005; O’Conaill & Frohlich, 1995). An important distraction may come from the frequent e-mails we get. As most of us experience, it is easy to get side-tracked by e-mails. We see a pop-up whenever a new e-mail comes in and we are inclined to react right away, or at least read it. However, each interruption takes about seven minutes of a person’s concentration. Checking your mail for instance eight times a day results in a time loss of more than one hour each day. Most people see e-mail as an urgent task, so they lose a lot of energy through diminished concentration, less focus and less flow experience. A tip to reduce getting side-tracked by e-mails, is to open e-mails only at specific time points, for instance twice a day, at 10 AM and 2 PM. If you do, reply instantly to mail you can deal with within two minutes and drag other mail to your result areas. You can deal with these mails as soon as you plan to work on that specific area.

Intervention

How can we develop an intervention to make sure that, in principle, everyone can reach this state of “high energy”, or refocusing of energy to become more productive? Although there is some evidence with respect to burnout, showing that an intervention aimed at restoring equity can be successful, especially when support from co-workers and supervisors is high (van
Dierendonck, Schaufeli, & Buunk, 1998), research investigating the effects of “energy management” interventions is scarce. We refer to energy management interventions in a broad sense, such as time-management courses, health interventions, and similar interventions that can have as a (main or side) goal to enhance energy. Most interventions are aimed at only one or two aspects (for a review see van der Hek & Plomp, 1997). Research regarding the use of time management techniques such as setting goals and priorities, making lists and schedules, and a preference for organization, were shown to be helpful in reducing tension and increasing job satisfaction, although a relation with job performance was not found (Macan, 1994). Furthermore, time management techniques seemed effective in reducing stress due to work-family conflict (Adams & Jex, 1999). A recent meta-analysis of stress management studies revealed that cognitive-behavioral interventions were more successful in reducing stress, than for instance relaxation and meditation (Richardson & Rothstein, 2008). Surprisingly, combining different interventions led to a reduced effect size. Also, longer programs were not more effective than shorter programs (Richardson & Rothstein, 2008). However, more research is needed to test the combined effects of different combinations of interventions, such as time management, relaxation and physical exercise in enhancing energy. Most of the research done so far, is aimed at reducing stress or the negative effects of burnout, while interventions specifically aimed at enhancing or maintaining energy are scarce (for an example of burnout prevention and engagement enhancement interventions, see Leiter and Maslach, 2000). This may in part be two sides of the same coin, although the overlap may not be perfect, as was found for the relation between burnout and engagement (cf. Schaufeli & Bakker, 2004). In their study, Schaufeli & Bakker (2004) found that burnout and engagement shared between 10 and 25 percent of variance, both were in part predicted by different variables, and also differed with respect to outcomes.
This may have important consequences for the effectiveness of interventions, depending on what the goal of the intervention is; either reducing/preventing burnout, or enhancing/maintaining a high energy level. This is a viable route for future research.

*Interventions in practice.* A problem that many trainers notice in organizations is that often people are sidetracked from their goals, and get feedback from their managers that goals are not met. Sometimes there is a lack of motivational energy, stress-management, time-management, problem solving ability and/or physical energy. An intervention may start by asking workers to extrapolate the results of their actions in the future for say five or ten years. This may make the unwanted end result of their day-to-day actions visible, and helps them to reflect on possible changes in order to redirect their energy. The workers can then find out what motivates him or her to give the full 100% in his/her work (cf. Csikszentmihalyi, 1997). A coach or trainer can then give some tools to enhance and maintain that motivation. In this way, competencies are used and developed instead of wasting energy on tasks that do not fit the person (i.e. Edwards, 1991). A personal energy plan can then be developed, including the use of formalized tools.

*Reflecting on long-term goals.* Reflecting on and determining what your long-term goals are, is an important prerequisite for effective energy management. A problem is that most people are driven by the need for instant success (doing small things, and getting rewarded immediately) which has a stronger pull than long-term success, with delayed gratification of rewards (e.g., Mischel, 1996; Muraven & Baumeister, 2000). In order to get bigger time-consuming jobs done that contribute to longer-term goals (e.g., publishing articles in top journals) plan a unit of time every day for these activities that are important, but not (yet) urgent. If organizations are capable to make parameters to measure progress toward long term goals, than this will have a powerful drive for workers to really act upon their main organizational values and goals on a daily basis.
Instead if workers do what the average person is inclined to do, they get average results (cf. Sonnentag, 1998).

Physical fitness. In order to maintain energy at the long term and maintain physical fitness (especially when one has a desk-job), it is important to make exercising a top priority. Research has shown that besides low-effort activities such as watching television, taking a bath, and social activities, physical activities in leisure time have a positive effect on work recovery (Sonnentag, 2001). Indeed, research has shown that regular physical activity can act as an anti-oxidant (Gomez-Cabrera, Domenech, & Viña, 2008), is related to better health (Shephard, 1997; Warburton, Nicol, & Bredin, 2006a, 2006b), emotional well-being (Steptoe & Butler, 1996) and that especially regular vigorous sports activities are related to mood improvement and stress reduction (Steptoe, Kimbell, & Basford, 1998; for a review see Salmon, 2001). In the long run, regular physical exercise has been related to lower mortality rates (Lee & Paffenbarger, 2000). It has been estimated that it is best to spend about 10% sporting time compared to working time. For a work week of forty hours, this means physical activities for about four hours a week would be best. Even several short bouts of ten minutes can be effective (Warburton et al., 2006b). As stress is the main cause of burn-out and diseases, it will certainly help if people are aware of the direct link between sport and stress reduction. Regular sports activity can thus mean that recovery during and after work is enhanced and this may mean staying energized at work (Thayer, 1987a, 1987b). Getting a new healthy habit is a matter of finding a ritual to do the action and get used to doing it by doing it often.

According to MacAuley (1993) it is relatively easy to integrate physical activity into daily life, by walking or cycling to work and including active tasks into everyday life, such as gardening. As work-related activity declines with modern living, the focus should be on sport
and exercise which involve continuous aerobic movements, such as jogging, cycling and swimming. However, for long term compliance the most important principle is that the chosen activity is enjoyable (Parfitt & Gledhill, 2004). Non-exercisers starting a work-out program should realize that most of the positive effects of regular exercise may only manifest in the long-term (Hsiao & Thayer, 1998; Salmon, 2001; Steptoe & Bolton, 1988).

Although most interventions occur at the individual level, a combination of changing the personal and managerial practices may be most effective (cf. Maslach et al., 2001). Although a lot of research is available regarding interventions at the individual level, interventions and research regarding the effect of interventions on the organizational level are scarce. A narrative of an intervention aimed at giving workers complete freedom of choice to work towards broad organizational goals suggested that this way of working can be highly effective both for the organization as well as the people in the organization (Semler, 1989, 1994, see also Rousseau (1997). Relatedly, and mentioned before, research regarding the effects of different kinds of leadership, such as servant leadership (Barbuto & Wheeler, 2006; Nuijten, 2009) can be insightful with regard to the effects on energy on followers. Future research should look at the combination of individual, health related, as well as organizational factors in order to determine how a high energy level can be maintained or enhanced.

Conclusion

Although energy seems a pervading subject, that all people have to deal with on a daily basis, research regarding this topic is scarce. A lot of theories have an implicit energetic connotation, without explicitly relating it to energy. This review showed that much can be learned from motivational theories and research regarding interventions. Future research could focus more on the role of energy, and explicitly research the effects on human energy level.
Possible antecedents and consequences of energy were mentioned in this article, such as personality and contextual factors. Also, the development and measurement of the effectiveness of interventions aimed at enhancing energy level deserves our research attention. In practice, people should become aware of the things that are energizing to them and capitalize on them more often. According to Csikszentmihalyi (1997, p. 40) energy level and flow can be enhanced as follows: “Keeping a diary or reflecting on the past day in the evening are ways to take stock systematically of the various influences on one’s moods. After it is clear which activities produce the high points in one’s day, it becomes possible to start experimenting, by increasing the frequency of the positive ones and decreasing that of others.”
