ABSTRACT

Introduction An ACR/EULAR task force released new criteria to classify rheumatoid arthritis at an early stage. This study evaluates the diagnostic performance of these criteria and algorithms by van der Helm and Visser in REACH.

Methods Patients with symptoms ≤12 months from REACH were used. Algorithms were tested on discrimination, calibration and diagnostic accuracy of proposed cut-points. Two patient sets were defined to test robustness; undifferentiated arthritis (UA) (n=231) and all patients including those without synovitis (n=513). The outcomes evaluated were methotrexate use and persistent disease at 12 months.

Results In UA patients all algorithms had good areas under the curve 0.79, 95% CI 0.73 to 0.83 for the ACR/EULAR criteria, 0.80, 95% CI 0.74 to 0.87 for van der Helm and 0.83, 95% CI 0.77 to 0.88 for Visser. All calibrated well. Sensitivity and specificity were 0.74 and 0.66 for the ACR/EULAR criteria, 0.1 and 1.0 for van der Helm and 0.59 and 0.93 for Visser. Similar results were found in all patients indicating robustness.

Conclusion The ACR/EULAR 2010 criteria showed good diagnostic properties in an early arthritis cohort reflecting daily practice, as did the van der Helm and Visser algorithms. All were robust. To promote uniformity and comparability the ACR/EULAR 2010 criteria should be used in future diagnostic studies.

METHODS

Diagnostic algorithms Three diagnostic algorithms were evaluated. The first is the new ACR/EULAR 2010 criteria set. The other two, the algorithms by van der Helm and the one by Visser, are existing, well-known models.

Validation cohort Clinical data used were from REACH. This ongoing, prospective, inception cohort study was set up in the greater Rotterdam area in July 2004. Patients were recruited either via their general practitioner, or via the outpatient rheumatology clinic of three hospitals at first consultation. Patients were included in case of one or more swollen joint or, in the absence of joint swelling, if they had two or more joints with pain or loss of movement with two or more of the following criteria: morning stiffness for more than 1 h; unable to clench a fist in the morning; pain when shaking someone’s hand; pins and needles in the fingers; difficulties wearing rings or shoes; a family history of RA; unexplained fatigue for less than 1 year. Patients were excluded if their symptoms resulted from trauma or overexertion, were for over 12 months, or if they were younger than 16 years.

A trained research nurse at the REACH clinic took a standardised history and conducted a physical examination at baseline, 6 and 12 months, including blood and urine samples. For the current analysis data from baseline and 1 year were used. Physical examination included the measurement of tender and swollen joints, using a 44 joint count. Laboratory variables included IgM-rheumatoid factor (ELISA), anti-cyclic

citrullinated peptide (Elia CCP on immunoCAP 250; Phadia Freiburg, Germany), C-reactive protein (local standards) and ESR (local standards), x-rays of hands and feet were assessed for bony erosions at baseline. For a detailed description of REACH, see Geuskens et al.14

**Statistical analyses**

To assess overall performance the prediction algorithms were tested on discrimination and calibration.15 Discrimination is the ability of an algorithm to differentiate correctly between patients with and without the disease. Calibration reveals the ability to estimate the probability of the diagnosis for individuals correctly by comparing the probability predicted by the algorithm and the observed probability. To evaluate discrimination receiver operating characteristic curves, including corresponding areas under the curve (AUC), were calculated. Calibration was evaluated using calibration plots and the Hosmer–Lemeshow test.15 The latter indicates good calibration if a non-significant result appears. To assess diagnostic performance of the algorithms sensitivity, specificity, positive predictive values (PPV) and negative predictive values (NPV) were estimated at cut-points proposed for treatment initiation among patients at risk of RA. For the ACR/EULAR 2010 criteria and Visser algorithm a score of 6 or more1,16 was used and for van der Helm a score of 8 or more17 was used. To test robustness this analysis was repeated among all patients included in REACH. This group had a lower previous disease probability by a factor of 2.4.

As a classifier for correct diagnosis two outcomes were evaluated at 1 year: the use of methotrexate and persistent disease, defined as synovitis present at physical examination after 1 year, or the use of disease-modifying antirheumatic drugs (DMARD) including biological agents. Patients with a definite alternative diagnosis such as gout were not classified as persistent disease. Synovitis was defined as joint swelling.

As a classifier for correct diagnosis two outcomes were evaluated at 1 year: the use of methotrexate and persistent disease, defined as synovitis present at physical examination after 1 year, or the use of disease-modifying antirheumatic drugs (DMARD) including biological agents. Patients with a definite alternative diagnosis such as gout were not classified as persistent disease. A complete case analysis was done.

**RESULTS**

**Validation cohort**

Up to 31 October 2008, 875 patients were referred to REACH and had 1-year follow-up. One hundred and 13 patients did not fulfil the inclusion criteria and 31 patients were lost to follow-up at baseline (see supplementary figure S1, available online only). Patients used in the development of the ACR/EULAR 2010 criteria were excluded (n=216).1 Table 1 reports baseline characteristics of all patients (n=513). Patients had a mean age of 50 years, 73% were women and the median symptom duration was 106 days (range 1–366 days). At baseline 48% (n=246) presented with synovitis. After 1 year, 148 of 513 used methotrexate, of whom 22 did not have synovitis at baseline, and 231 of 513 patients had persistent disease, of whom 59 did not have synovitis at baseline.

**Discrimination**

Table 2 shows AUC of each diagnostic algorithm for both outcomes. In undifferentiated arthritis (UA) patients (n=231) the AUC for methotrexate use were comparable, with overlapping 95% CI, 0.79 (95% CI 0.73 to 0.83) for the ACR/EULAR 2010 criteria, 0.80 (95% CI 0.74 to 0.87) for the van der Helm algorithm and 0.83 (95% CI 0.77 to 0.88) for the Visser algorithm. For persistent disease the AUC were 0.77 (95% CI 0.71 to 0.85) for the ACR/EULAR 2010 criteria, 0.78 (95% CI 0.71 to 0.85) for the van der Helm algorithm and 0.77 (95% CI 0.71 to 0.85) for the Visser algorithm. In all patients (n=513) the AUC were comparable for both outcomes, with slightly better performance of the van der Helm algorithm; 0.83 (95% CI 0.84 to 0.91) and 0.83 (95% CI 0.79 to 0.87).

**Calibration**

Calibration plots of all diagnostic algorithms are shown in figure S2 (see supplementary figure S2, available online only). In UA patients (n=513) calibration was worse than in all patients, although the Hosmer–Lemeshow test was not significant for any of the calibration plots. All algorithms calibrated well in all patients (n=513), confirmed by the Hosmer–Lemeshow test.

**Evaluating diagnostic performance using proposed cut-points**

To identify patients in need of treatment proposed cut-points were tested in UA patients. The ACR/EULAR criteria showed a sensitivity of 0.74 (95% CI 0.65 to 0.82) and a specificity of 0.66 (95% CI 0.54 to 0.76), with the cut-point of 6 or higher using methotrexate as a classifier for correct diagnosis (table 3). The Visser algorithm and the van der Helm algorithm had a lower sensitivity, 0.47 and 0.59 for the Visser algorithm for both outcomes and 0.08 and 0.10 for the van der Helm algorithm. Specificity was higher: 0.93 for the Visser algorithm and 1.0 for the van der Helm algorithm.

The PPV is the probability that a patient has the disease if the test is positive. The van der Helm algorithm had the highest PPV; 1.0. The NPV is the opposite probability and was highest for the ACR/EULAR criteria with 0.65 for methotrexate use and 0.46 for persistent disease, slightly higher than the Visser algorithm.

**DISCUSSION**

The results of our study show that the new ACR/EULAR 2010 criteria could aid diagnostics in early arthritis patients. They had good overall performance, with a sufficiently high AUC and good performance of the proposed cut-point of 6 for persistent disease, which could be considered RA. The other algorithms performed well when tested for discriminatory properties.

ACR, American College of Rheumatology; EULAR, European League Against Rheumatism; NPV, negative predictive value; PPV, positive predictive value; UA, undifferentiated arthritis.

We defined two outcomes; methotrexate use similar to the definition of the ACR/EULAR 2010 and persistent disease (either synovitis or DMARD use at 12 months). This may have led to missclassification in two ways. Patients could be classified as true positive because they were still using methotrexate or other DMARD at 12 months, whereas in fact some patients may not need treatment. Likewise, patients may have had episodes of arthritis with no episode or DMARD use at 12 months, while later on they developed persistent arthritis.

In conclusion, the new ACR/EULAR 2010 criteria showed good diagnostic properties in an early arthritis cohort reflecting daily clinical practice, as did the van der Helm and Visser algorithms. All were robust. To promote uniformity and comparability we would suggest using the ACR/EULAR 2010 criteria in future diagnostic studies.

Acknowledgements  The authors would like to thank all patients and general practitioners who participated as well as the research nurses, rheumatologists and rheumatologists (other than the authors) who contributed to the REACH cohort.

Funding  Data management was partly funded by the Dutch Arthritis Association.

Competing interests  None.

Ethics approval  This study was conducted with the approval of the medical ethics committee at Erasmus MC.

Provenance and peer review  Not commissioned; externally peer reviewed.
