Leadership and Meaningful Work in the Public Sector

There have been many important studies on leadership in the public administration discipline; however, scholarly inquiry still lags behind related disciplines such as psychology and business administration. This article helps fill that gap by analyzing the role that public leaders play in making work more meaningful for their employees, which, in turn, has a positive influence on employee job outcomes. Specifically, the authors analyze the mediating role of work meaningfulness in the relationships between leader-member exchange and organizational commitment, work effort, and work-to-family enrichment. Samples from education, health care, and local government are used. Results show that leadership strongly influences work meaningfulness, which, in turn, influences job outcomes. In addition, the impact and extent of leadership and work meaningfulness are higher in health care and education than in local government. The results emphasize the importance of leadership and meaningful work in the public sector.

There have been a number of important studies on leadership in the public administration, and more specifically public management discipline (see, e.g., Fernandez 2005; Kim 2002; Terry 2002; Wright and Pandey 2010). However, this area of scholarly inquiry still lags behind related disciplines such as business administration and psychology (Trottier, Van Wart, and Wang 2008). Hansen and Villadsen recently concluded that compared to other disciplines, “leadership theory has generally received little attention in public management research” (2010, 247). In a recent literature review on administrative leadership, Van Wart (2013) was more nuanced, stating that there has been substantial development. However, he also noted that “fragmentation and conflicting nomenclature continue to be a problem, but at a more sophisticated level” (2013, 13). More specifically, he noted that for leadership studies in public administration, “well-designed studies would be welcomed by various public sector industries, jurisdictions, and levels of administration” (17).

In response to the call for well-designed leadership studies in public administration, this article focuses on developing a theoretical model relating leadership, the meaning of work, and the resulting job outcomes. This model will be tested using data collected in three public sector settings: health care, education, and local government.

In the theoretical model, we build on the well-known notion of leader-member exchange (LMX), which has its roots in social exchange theory (Blau 1964). LMX describes the quality of the relationship between a leader and a member (Graen and Uhl-Bien 1995). LMX research indicates that leaders develop differentiated relationships with their employees. In relationships characterized by low LMX, there is essentially an economic exchange between employer and employee (i.e., time is exchanged for money). In high-quality relationships, mechanisms of reciprocity and social exchange become effective: the leader and the employee trust each other, employees feel valued by their supervisor, and effective working relationships develop. In general, high LMX has several important positive job outcomes, such as increased job satisfaction, higher performance, and lower staff turnover (Dulebohn et al. 2012).

However, a piece of the puzzle appears to be missing when examining LMX and its outcomes. As Gerstner and Day (1997, 835) observed, although there is evidence that a better employee–supervisor relationship enhances outcomes, this association needs further examination. They suggested examining variables that potentially mediate the relationship. A number of private sector studies have examined possible mediating mechanisms, and these often use the notion of empowerment. However, results are inconsistent.

This article focuses on developing a theoretical model relating leadership, the meaning of work, and the resulting job outcomes.

While Aryee and Chen (2006) found that empowerment mediated the relationship between LMX and job outcomes, Liden, Wayne, and Sparrowe (2000, 407) failed to find such a relationship. Further, Harris, Wheeler, and Kacmar (2009) argued that the relationship between LMX and job outcomes was moderated rather than mediated by psychological empowerment.

This article analyzes work meaningfulness, one of the dimensions of psychological empowerment, as a potential mediator between LMX and its outcomes. This approach seems more promising than using the broad concept of empowerment. The hypothesis tested is that when employees and managers have a good relationship (i.e., high LMX), leaders will provide their employees with greater insight into how the organization works and give them more responsibility. It seems reasonable to expect this to positively influence employees’ job experience and the possibility of their making a difference in their work. In turn, one could expect this to have positive outcomes (see also Liden, Wayne, and Sparrowe 2000). In this article, the focus is on two important outcomes inside the work context—organizational commitment and work effort—and one important outcome outside the work context—work-to-family enrichment.

This article contributes to the literature by (1) focusing on leadership in the public sector using an explicit theoretical model; (2) analyzing one specific dimension of empowerment, work meaningfulness, to explain the relationship between LMX and certain outcomes; and (3) testing the developed model using three independent public sector samples drawn from education, health care, and local government. The article answers the following research question: To what extent does the meaningfulness of work mediate the relationship between LMX and outcomes inside the work context—organizational commitment and work effort—and outside the work context—work-to-family enrichment?

In the following section, we discuss the theoretical framework. The next section describes the method used to test our hypotheses, and then the results are discussed. We conclude by discussing the contribution of this article to the public management literature on leadership.

**Theoretical Framework**

**Background on Leadership**

In broad terms, there are two contrasting views on leadership in organizations (Howell and Hall-Merenda 1999). One view is leader focused and attempts to explain performance by analyzing specific leadership behaviors and linking these directly to outcomes. This view is adopted in theories on transactional and transformational leadership (for a recent public sector example, see Wright and Pandey 2010). The second view is relationship based, analyzing how leaders interact with their employees. This view is best exemplified by the concept of leader-member exchange (Howell and Hall-Merenda 1999, 680; Wang et al. 2005, 420). Given the aim of this research—to analyze the role of work meaningfulness in the relationship between LMX and outcomes—the second view is most appropriate.

LMX is defined as the quality of the relationship between a leader (supervisor) and a member (employee) (Gaen and Uhl-Bien 1995). Whether LMX is a management practice or a leadership practice is open to debate (Zaleznik 1977), but we follow mainstream LMX research and view LMX as a leadership practice (Dulebohn et al. 2012; Graen and Uhl-Bien 1995; Liden, Sparrowe, and Wayne 1997).

The impact of LMX on several outcomes has been studied extensively. In a meta-study, Gerstner and Day (1997) noted that LMX was positively related to several work outcomes, such as supervision satisfaction, overall satisfaction, and commitment. More recently, Dulebohn et al. (2012) conducted a meta-analysis of 247 studies and found a possible 16 important outcomes of LMX quality, such as behavioral outcomes (lower turnover intention and higher job performance), attitudinal outcomes (higher job satisfaction and organizational commitment), and perceptual outcomes (higher perceived procedural justice and empowerment).

There are some studies that examine the influence of LMX on variables outside of work, such as work–life balance and work–family arrangements. For instance, Brunetto et al. (2010) found that LMX predicted perceptions of work–family conflicts in particular for public sector employees. However, this area is far less studied than work-related outcomes (Culbertson, Huffman, and Alden-Anderson 2009).

**Background on Meaningfulness**

In this article, the concept of meaningfulness at work is considered as a potential mediator between LMX and outcomes. Here, it is useful to first describe the background of meaningfulness. We will discuss the background of the meaningfulness concept, linking it to various literature streams, such as work and organizational sociology (particularly alienation studies) and work and organizational psychology (empowerment, job characteristics model, engagement).

The concept of meaningfulness builds on the alienation tradition that comes from the sociology of work and organization field. Alienation refers broadly to a sense of social estrangement and an absence of social support or meaningful social connection. The intellectual roots of the alienation concept are found in the work of Karl Marx ([1844] 1961), who focused on objective work alienation: workers become alienated when they do not own the means of production or the resulting product. Many sociologists writing on alienation draw on Marx, although, in contrast to Marx, they focus on subjective work alienation: alienation as perceived by the worker (DeHart-Davis and Pandey 2005).

Social scientists have used the (subjective) alienation concept in various studies, and a number of meanings have been attributed to the term. In an attempt to provide clarity, Seeman (1959) broke down these meanings into five alienation dimensions: powerlessness, meaninglessness, normlessness, social isolation, and self-estrangement. Of these dimensions, powerlessness and meaninglessness are considered to be particularly important (DeHart-Davis and Pandey 2005; Tummers 2011). This article focuses on the role of meaningfulness/meaninglessness. In a work setting, meaninglessness can occur “when workers are not able to understand the complex system.
of goals in the organization and its relationship to their own work” (Kanungo 1982, 26).

The meaninglessness/meaningfulness of work concept can also be found in the work and organizational psychology field. Here, it is first related to the literature on psychological empowerment. Spreitzer (1995, 1443) noted that meaning of work is one of four components of psychological empowerment. It is described as the fit between the requirements of a work role and one’s own beliefs, values, and behaviors. In a recent review, Maynard, Gilson, and Mathieu (2012) concluded that of the four components of psychological empowerment, meaning of work had the strongest relationship with job satisfaction (see also Liden, Wayne, and Sparrowe 2000). Overall, it was found that certain components of psychological empowerment are potential mediators between various work antecedents (such as leadership) and work outcomes (such as job satisfaction and organizational commitment). This article follows a similar line of reasoning in analyzing work meaningfulness as a potential mediator between LMX and outcomes.

Next, the concept of meaningfulness is also discussed in the job characteristics model of Hackman and Oldham (1980). The meaningfulness experienced in work is seen as a key psychological state that mediates the relationships between core job characteristics and outcomes. In a meta-analysis, Humphrey, Nahrgang, and Morgeson (2007) found that experienced meaningfulness was the primary mediator between job characteristics and outcomes. As such, meaningfulness seems to be an important mediator when relating job characteristics to outcomes (see also Arnold et al. 2007; Clausen and Borg 2011).

Work meaningfulness is also related to the concept of work engagement, although these concepts also differ notably. Schaufeli et al. defined engagement as “a positive, fulfilling work-related state of mind that is characterized by vigor, dedication, and absorption” (2002, 74), noting that engaged employees have a sense of energetic and effective connection with their work activities and see themselves as able to deal well with the demands of their jobs. In this article, work meaningfulness is defined as an employee’s perception that he or she is able to understand the complex system of goals in the organization and its relationship to his or her own work; this has both similarities as well as differences with the work engagement concept. On the one hand, both the meaningfulness and engagement concepts refer to work-related attitudes, and both are positive psychological states. However, while engagement refers to job demands in relation to an employee’s own abilities, meaningfulness refers to the goals of the organization in relation to an employee’s own work. One could argue that the concepts are related in the sense that meaningful work can result in greater employee engagement (Olivier and Rothmann 2007).

A few remarks can be made regarding analyzing the role of meaningfulness specifically in public organizations. However, it must be stated that making a simple distinction between public organizations, on the one hand, and private organizations, on the other, seems overly simplistic (Rainey and Bozeman 2000). Besides their public, semipublic, or private legal status, many characteristics influence organizations and their working environments, such as size, location, environment, and function. Notwithstanding this remark, it can be argued that public organizations have considerable goal complexity and goal ambiguity (Jung 2011; Rainey and Bozeman 2000). In an organization with substantial goal complexity and ambiguity, it could be difficult for employees to understand the contribution of their specific work to the organization or to society—in other words, to feel that their work is meaningful. On the other hand, many people chose to work in the public sector because they aim to do meaningful work and contribute to society (Perry and Hondeghem 2008). Hence, studying work meaningfulness—and ways to improve it—could be quite important in public sector settings.

**Leadership, Meaningfulness, and Outcomes**

In this section, the relationships between LMX, meaningfulness, and three relevant outcomes are analyzed. Figure 1 depicts the conceptual model outlining the relationships between the variables in this article.

We first analyze how LMX influences meaningfulness at work. One would intuitively expect the degree of LMX to positively influence experienced meaningfulness. When the relationship between leaders and employees is of high quality, employees are given greater decisional latitude and provided with more opportunities to participate. This makes it easier for them to make meaningful contributions to the organization and to society and increases their understanding of their role within it. Hence, it can enhance their experienced meaningfulness at work (see also Aryee and Chen 2006).

On this basis, one can consider how the outcomes are influenced. First, we look at two important effects on the work level: affective organizational commitment and work effort. These effects were selected given their importance for organizational performance (McAllister 1995; Meyer et al. 2002).

Affective organizational commitment is defined as an “employee’s emotional attachment to, identification with, and involvement in the organization” (Allen and Meyer 1997, 11). Employees who experience affective commitment stay with an organization because they genuinely want to, because they can identify with that organization. Following Gerstner and Day (1997), one would expect the
level of LMX to be positively related to the degree of organizational commitment. Further, if employees feel that their work is meaningful, this will increase their organizational commitment—and they will stay with their organization because they want to (Pierce and Dunham 1987).

Work effort refers to the extent to which employees exert effort that goes beyond their formal job requirements (Gould-Williams 2004). It seems that, for organizations, it is paramount that employees “go the extra mile.” One could expect the level of LMX to be positively related to work effort. Here, Kacmar, Zivnuska, and White (2007) showed that LMX significantly influenced the level of self-assessed work effort. Moreover, we also expect meaningfulness to positively influence the effort that workers put into their work. Cummings and Manring (1977) found that meaningfulness was positively related to work effort and performance. Further, Arnold et al. noted that “higher purpose [or less meaninglessness] was associated with increased job satisfaction, perceptions of unit cohesion, and work effort” (2007, 195).

In addition to organizational commitment and work effort, an outcome outside of work is considered: work-to-family enrichment. Work–family researchers have examined both negative and positive relationships between work and family life. Initially, the main focus was on work–family conflict, although more recently, the positive relationships between work and family have been emphasized through work-to-family enrichment (Greenhaus and Powell 2006). Work-to-family enrichment occurs when resources from the former improve performance in or positively affect the latter. This article focuses on the affective dimension of work-to-family enrichment, that is, “when involvement in work results in a positive emotional state or attitude which helps the individual to be a better family member” (Carlson et al. 2006, 140). For instance, work-to-family enrichment occurs when an employee feels valued at work (e.g., because he or she can help students with their theses) and, because of this, is in a good mood at home. We would expect high LMX to increase work-to-family enrichment (see also Bernas and Major 2000). Further, work meaningfulness may create a positive emotional state and, consequently, increase the likelihood that work-to-family enrichment occurs (Hackman and Oldham 1980).

In the foregoing discussion, a link was established between both LMX and meaningfulness and three outcomes. Further, it was hypothesized that LMX influences meaningfulness. Given its attitudinal foundations, meaningfulness is seen as closer than LMX to the outcome dimensions, and therefore it should serve as a mechanism through which LMX influences the outcomes dimensions (see also Aryee and Chen 2006). However, we do not expect the relationship between LMX and the outcomes to be fully mediated by the level of meaningfulness. Rather, we expect the level of LMX experienced by employees to also have a direct effect on the outcomes. For example, if employees experience high levels of LMX, they will work harder, not only because of the increased meaningfulness but also because they want to “return the favor” (Graen and Uhl-Bien 1995). Thus, overall, we expect the relationship between LMX and the studied outcomes to have both direct and indirect (through meaningfulness) components.

Overall, we expect the relationship between LMX and the studied outcomes to have both direct and indirect (through meaningfulness) components. Based on the foregoing, the following hypotheses are formulated:

Hypothesis 1a: LMX has a positive direct effect on organizational commitment.

Hypothesis 1b: LMX has a positive indirect effect, through the level of meaningfulness, on organizational commitment.

Hypothesis 2a: LMX has a positive direct effect on work effort.

Hypothesis 2b: LMX has a positive indirect effect, through the level of meaningfulness, on work effort.

Hypothesis 3a: LMX has a positive direct effect on work-to-family enrichment.

Hypothesis 3b: LMX has a positive indirect effect, through the level of meaningfulness, on work-to-family enrichment.

Method
Testing the Proposed Model Using Survey Data from Three Sectors

This section describes the survey procedures used to test the hypotheses. As suggested by Perry (2012), we analyzed our procedures using the “total survey error framework” of Lee, Benoit-Bryan, and Johnson (2012). The total survey error framework assesses the quality of the techniques used in conducting a survey. In using this framework, shown in table 1, researchers aim to increase the quality of their studies. In order to improve the reliability and validity of the findings, we have taken various measures in order to keep the possible errors identified by Lee, Benoit-Bryan, and Johnson (2012) to a minimum.

Survey data from three sectors were collected: education, health care (midwives), and local government (municipalities). These sectors were chosen because they potentially differ in their degree of meaningfulness: whereas work in education and health care is often perceived as meaningful, it is sometimes harder to see working for local government as contributing to society. This difference could influence the mediating mechanisms.

We initially established contact with organizations and asked whether they would agree to participate in the research project. We then contacted respondents by e-mail, including a link to the questionnaire, which also described the research project and its objectives and stressed anonymity. Two follow-up mails were sent to increase the response rate.

In the health care sector, our sample consisted of 1,278 midwives. We chose to focus particularly on midwives given that they were expected to perceive their work as very meaningful.1 We received 790 completed questionnaires, for a response rate of 61 percent. Of the valid responses, 97.2 percent were from women, and their average age was 40. This is consistent with national figures for midwives, which is a traditionally
female occupation (97 percent female) with a mean age of 37 (Hingstman and Kenens 2011). For the local government group, we surveyed employees from the two largest Dutch municipalities (Amsterdam and Rotterdam). We invited 473 employees to participate and received 229 completed questionnaires. Again, the responding sample (54.1 percent female, average age 43) was somewhat similar to the Dutch municipal averages: 46 percent female (Netherlands Ministry of the Interior 2010), with an average age of 43 (Statistics Netherlands 2010). In the education sector, we invited 881 employees from a school for intermediate vocational education and 200 university employees. The overall response rate was 29 percent (313 employees). Here, the average age of the respondents was 47 years, and 63.8 percent were female. This is again somewhat similar to the Dutch education averages: 62 percent female and average age 43 (Statistics Netherlands 2010).

For all three sectors, we performed a nonresponse analysis. Results showed that employees did not participate because of a lack of time, technical difficulties completing the online instrument, and the fact that they already had to fill out a lot of questionnaires. This analysis does not suggest any severe bias in our sample.

**Measures**

The variables were all measured using five-point Likert scales, where 1 indicated very weak support for the item statement and 5 indicated very strong support.

**Leader-member exchange.** The LMX scale of Liden, Wayne, and Stilwell (1993), which is made up of seven items, was used. A sample item is “I feel that my immediate supervisor understands my problems and needs.” Cronbach's alpha for the scale was .919.

**Meaningfulness.** The concept of meaningfulness is based on the alienation tradition, which considers its opposite: meaninglessness. We used five items from Mottaz’s (1981) often-applied scale. We retained all of the items but reversed the answers (recoded, R) in the statistical analyzes. A sample item is “I often wonder what the importance of my job really is” (R). Cronbach's alpha was .815.

**Organizational commitment.** Allen and Meyer (1990) developed a number of items to measure affective organizational commitment. We used the five best-fitting items from this scale. A sample item is “I feel a strong sense of belonging to my organization.” Cronbach's alpha was .893.

**Work effort.** We used the eight-item work-effort scale developed by Gould-Williams (2004) to measure employee discretionary effort. We used the five best-fitting items. A sample item is “I volunteer for things that are not part of the job.” Cronbach's alpha was .683.

**Work-to-family enrichment.** We included the three-item affect dimension of work-to-family enrichment based on Carlson et al. (2006, 140). A sample item is “My involvement in my work puts me in a good mood and this helps me be a better family member.” Cronbach's alpha was .926.

**Control variables.** We also included commonly used control variables: gender, age, supervisory tasks (yes/no), number of working hours, children living at home (yes/no) (possibly relevant given the focus on work–family interference), and level of education (1 = primary school, 2 = secondary school, 3 = intermediate vocational education, 4 = higher vocational education, 5 = academic education, 6 = postgraduate, e.g., specialization or PhD).

**Measurement Quality and Data Analysis**

Confirmatory factor analysis (CFA) was used to test the hypotheses, followed by structural equation modeling (SEM). The CFA and SEM techniques are often used in psychological research but
are relatively new to most public administration scholars (but see, e.g., Tummers and Bekkers, forthcoming; Wright, Moynihan, and Pandey 2012). Therefore, we discuss a number of the analyses’ characteristics in some detail.

Confirmatory factor analysis is a technique used to test the factor structure of latent constructs based on theory and prior research experience. This is appropriate here given that previous analyses have already explored some of the variables, such as LMX. CFA has several advantages over exploratory factor analysis, such as more stringent psychometric criteria for accepting models, and this improves both validity and reliability (Brown 2006).

A CFA results in a measurement model being specified. This model specifies the number of factors and shows how the indicators (i.e., items) relate to the various factors. For instance, it shows how the items measuring work-to-family enrichment relate to the latent construct of work-to-family enrichment. The results of the CFA confirm the factor structure described earlier. The standardized coefficients all had adequate values between 0.514 and 0.984 (p < .001). This shows evidence of convergent validity—that is, items that tap the same latent construct are related to each other (Kline 2010).

The measurement model is a precursor for the SEM analyses in which a structural model is constructed showing how the various latent factors relate to each other (see the Results section). In an SEM analysis, a total model can be tested in which variables can be both dependent and independent, one of the advantages over regression analyzes. Given that in our model, the work meaningfulness variable is both dependent, being hypothetically influenced by LMX, and independent, hypothetically influencing outcomes, this is appropriate.

The data analysis was carried out using Mplus (Muthén and Muthén 1998–2010). Data are often non-normally distributed when employing surveys, but this reality is frequently ignored by researchers. Here, the non-normal distribution of the data was taken into account by using the weighted least squares with a robust estimator approach available within Mplus.

The data for all items were collected from individual respondents and thus are potentially subject to common method bias (Podsakoff et al. 2003). Although a recent study showed that “in contrast to conventional wisdom, common method effects do not appear to be so large as to pose a serious threat to organizational research” (Lance et al. 2010, 450), we have addressed this potential problem in various ways. In the survey design, we spread the items relating to different variables across various sections of the questionnaire. Further, we conducted two sets of CFAs to check for common method bias in the data, comparing the hypothesized structure with a one-factor model. The analyses provide evidence against there being a bias stemming from common method variance. Hence, common method bias does not appear to be a serious concern.

### Results

#### Descriptive Statistics

Descriptive statistics and correlations of the variables are presented in table 2. Respondents were fairly positive about the support they received from their leaders and reported a high level of work meaningfulness. Table 3 shows the descriptive statistics for respondents employed in the various sectors. There are significant differences between the groups. Health care employees have the highest scores for all the variables. Employees working in education were generally slightly more positive than municipal employees.

#### SEM Results

The results presented in table 4 show that for the overall model, a good model fit was achieved (CFI = .987, TLI = .985, RMSEA = .045). The results indicate that LMX has a direct effect on all the outcome variables. This offers support for hypotheses 1a, 2a, and 3a.

864 Public Administration Review • November | December 2013
The findings show that the mechanisms that connect LMX and outcomes vary between sectors. In health care, LMX has both a direct effect on outcomes and an indirect one through meaningful work. In education, meaningfulness is an even more important mechanism: it fully mediates the relationships between LMX and work-to-family enrichment. This emphasizes the importance of meaningful work. This is significant, as many organizational behavior and leadership scholars downplay the importance of meaningful work. Th is study contributes to understanding leadership in public sector organizations in two ways: first, as encouraged by Van Wart (2013), by developing an explicit theoretical model and then testing this with data from various public sector settings; and second, by focusing on the dynamics and mechanisms of leadership, analyzing the mechanisms at play to explain how a better relationship between employees and their leaders boosts outcomes. More specifically, the role of work meaningfulness was analyzed as a potential mediator between LMX and outcomes, both inside and beyond the work context. The results indicate that the meaningfulness of work is an important mediator between leadership and outcomes, in line with theoretical expectations. When employees and managers have a good relationship (i.e., high LMX), this positively affects employees’ perceptions of making a difference in their work and seeing the relationship of their work to the larger organization. It may be that in such situations, leaders provide employees with greater insight into how the organization works and give them more responsibility. In return, this results in higher organizational commitment and greater work effort and enriches work-to-family crossover. This emphasizes the importance of meaningful work. This is significant, as many organizational behavior and leadership scholars downplay the importance of meaningful work (but see May, Gilson, and Harter 2004). Organizational behavior scholars tend to focus on autonomy or job control (see for instance Deci and Ryan 2004). While the role of participative management is well researched in leadership theory (e.g., Kim 2002), there is much less research on meaningful work. The current research suggests that the role of meaningfulness is significant and an important study topic regarding leadership issues in the public management discipline. An interesting avenue here could be to combine the leadership literature concerning meaningfulness with insights from public service motivation (Vandenabeele 2008).

The results indicate that the meaningfulness of work is an important mediator between leadership and outcomes, in line with theoretical expectations.

* p < .05; ** p < .01; *** p < .001.

Notes: Unstandardized coefficients are presented (standard errors in parentheses). The control variables are not reported because of space limitations but can be provided by the authors. H = health care; M = municipalities; E = education.

3a. LMX is also significantly related to meaningfulness. In turn, meaningfulness has a significant relationship with all the outcome variables. The results indicate that the relationships between meaningfulness and the outcome variables are stronger than those between LMX and the outcome variables. We also tested for indirect effects: of LMX, through meaningfulness, on commitment, on work effort, and on work-to-family enrichment. All of these indirect paths are significant, supporting hypotheses 1b, 2b, and 3b. Overall, the levels of explained variance are quite high. First, regarding commitment, the model explains 40.4 percent of the variance. This is attributable to the direct and mediated effects of LMX and to the significant control variables (gender and number of working hours). Women and those who work long hours reported higher levels of commitment. The level of work effort variance explained is 23.8 percent. Gender, supervisory tasks, number of working hours, and the direct and mediated effect of LMX all contribute to explaining this variance. Women, supervisors, and those who work the most hours reported higher levels of work effort. The model explains 11.6 percent of the variance in work-to-family enrichment. The direct and mediated effects of LMX are significant, as well as the gender and number of working hours control variables. Women
both work effort and work-to-family enrichment. In other words, if teachers have a good relationship with their supervisor, this will increase the meaningfulness of their work, and this will have positive effects for the organization and for the employee. When it comes to local government, LMX has a direct relationship only with commitment and work-to-family enrichment, and meaningfulness does not play a significant role as a mediator. It would seem, particularly in education and also in health care, that the level of meaningfulness is an important predictor of outcomes, whereas in local government, employees seem to be committed and experience work-to-family enrichment regardless of the meaningfulness they perceive in their jobs. It could be that employees in health care and education chose to work in these sectors because they want to perform meaningful work, whereas in local government, employees have other motives, such as job security and regular pay increases, reducing the role of meaningful work (Jurkiewicz and Massey 1996). This argument would fit the descriptive statistics, which show that perceived meaningfulness is lower in the local government sector than in the other two investigated. A further possibility is that it could also be caused by a difference in the nature of supervisor–employee relationships among sectors; managing a health care professional is obviously quite a different task than managing a local government employee (see also Mintzberg 1998).

We end this article by discussing some of its limitations. First, some of the variables in the data set demonstrated limited variability. This is particularly the case for the variable meaningfulness. Although all possible scores are represented in the data set, attenuated ranges could result in either over- or underestimates of effect sizes. It could be that the high mean score for meaningfulness is a consequence of conducting the study in the public sector. That is, employees typically opt to work in the public sector because they want to contribute to society, that is, to do meaningful work. It would be interesting to compare public and private sector employees in future studies. Another methodological limitation is the use of cross-sectional data. As such, assumptions based on theoretical arguments are made about the likely direction of causality, moving from leadership through meaningfulness to outcomes. Future studies could employ longitudinal or experimental designs that could test the causality of these relationships.

Concluding, our empirical results emphasize the importance of leadership in the public sector. In line with Wright and Pandey (2010, 86), we note that “management matters” (Pandey, Coursey, and Moynihan 2007; Rainey and Steinbauer 1999; see also Hennessy 1998; Knies 2012). Our research findings highlight the importance of studying and improving leadership in the public sector and, especially, the need to relate leadership with meaningful work. Further, by testing explicit theoretical models in various parts of the public sector, this study highlighted important differences between various parts of the public sector.

Notes
1. Our results therefore are applicable only to the population of midwives, not to health care workers in general (matching target population and sampling frame; see Lee, Benoit-Bryan, and Johnson 2012).
2. The seven items in the original scale were measured in the questionnaire. However, given that CFA test is often more stringent than the Cronbach’s alpha reliability measure (Kline 2010), two items were taken out in order to improve the fit. This method was also applied to the scales for organizational commitment and work effort to improve fit.
3. The scores for the control variables are not shown in table 4 because of space restrictions. Where the control variables were significant, this is noted in the text.
