[Abstract: 216 words]

Aim: The aims of this paper are to identify the determinants of the ‘intention to leave’ (ITL) of nurses working at a general hospital, and to provide recommendations for various hospital stakeholders to prevent premature leave to various post-exit destinations.

Background: Nurse turnover is a serious problem, especially given the increased need for professional medical care due to demographic changes, and puts pressure on health care management. In order to meet future requirements for nursing staff, it is of utmost importance to empirically study nurses’ intention to leave either their department or hospital, and to identify the determinants of these various intentions to leave.

Methods: A cross-sectional survey was completed by 318 nurses working at various departments at a general hospital in Eindhoven, the Netherlands. Data were collected in May 2011. Using binary regression analysis, various determinants of nurses’ reported post-exit career choices could be identified.

Conclusions: Nurses’ intention to leave is determined by the nurse’s general satisfaction with management and leadership quality, pay and benefits, job satisfaction and work-to-home interference issues, but not by (career) development opportunities. However, various post-exit choices are influenced by various determinants.
Implications for nursing management: Preventing nurses from leaving their department or hospital requires careful attention for management and leadership quality, pay and benefits, job satisfaction, and home-work balance issues, especially for line managers that actually supervise nurses on a day-to-day basis.

Keywords: nurse turnover, intention to leave, turnover intentions, nurse post-exit destinations

Introduction

Both the professional and academic nursing literature, report a high and rising shortage of nurses throughout the world (Chan, 2008; Sawatzky & Enns, 2012). The problem is one of both supply and demand: increasing patient loads (particularly induced by baby boomer patients; North, Erasmussen, Hughes, Finlayson, Ashton, & Campbell, 2005), decreasing enrolment in nursing education programs (Buerhaus, Auerbach, & Staicher, 2007) and high turnover (Van der Heijden, Van Dam, & Hasselhorn, 2009) all contribute to the serious shortage in the nursing sector.

Shortage of nurses negatively affects patient outcomes and cost containment in health care (Aiken, Clarke, Sloane, Sochalski, & Silber, 2002). Patient outcomes are affected because of higher patient-to-nurse ratios, longer waiting times, and inability for nurses to administer appropriate care; cost containment is negatively affected because of initial decreases in new employee productivity and diminished morale of retaining nurses (Rivers, Tsai, & Munchus, 2005; Sawatzky & Enns, 2012).

Of the determinants of nurse shortage, turnover is supposed to be more amenable to managerial and administrative action than demographic developments and young professional's career choices are. Therefore, various authors have explored the determinants of turnover (Brown, Fraser, Wong, Muise, & Cummings, 2012; Derycke, Vlerick, Burnay, Decleire, D’Hoore, & Hasselhorn, 2010; Sawatzky & Enns, 2012; Van der Heijden, Van Dam, & Hasselhorn, 2009). However, a full understanding of the phenomenon of nurse turnover, both in terms of determinants, as well as in terms of explanations of nurses’ choices for specific post-exit choices, is lacking. Some studies emphasize occupational turnover (attempting to explain why nurses decide to leave their profession), other studies attempt to explain nurses’ choice to change jobs within the same profession, but a more rigorous explanation of how various post-exit destinations are related, and, more importantly, how to explain nurses’ choices for various post-exit destinations, is lacking. This study tries to fill this gap in the literature.

In this contribution, we aim to explain nurse turnover by analyzing underlying nurses’ intentions to leave as immediate determinants of actual ‘exit’ behavior (Liou, 2009; Mobley, 1979). The data that is used in the analysis is perceptual in nature: it was gathered using a survey among nurses working at a specific hospital, Catharina Hospital in Eindhoven, the Netherlands. Reason for using
perceptual data (as opposed to, for instance, an analysis of motivations of nurses that have actually changed jobs) is that, from a managerial point of view, it may be more interesting to assess intentions as opposed to post-hoc reasons as the former are amenable to change whereas the latter are not. Moreover, empirical studies have reported, in line with Fishbein (1979) and Ajzen & Fishbein (1980) theoretical claims, that an intention to perform a specific behavior is an immediate determinant of actually performing an action the intention refers to (Hasselhorn, Muller, & Tackenberg, 2005).

More specifically, we have empirically investigated nurses’ intention to leave to various post-exit choices using a sample of nurses from a specific general hospital. Our objective is to empirically test a number of hypotheses based upon existing literature; moreover, in this study we attempt to explain not only the intention to leave itself, but also the choice for specific post-exit choices, for instance, to switch jobs within one and the same hospital, to try to find a new employer, such as a medical practitioner practice or community care, just to mention a few examples.

**Intention to leave: literature review, conceptual framework and hypotheses**

**Introduction**

Critical conditions of an ageing workforce and increased competition among employers for talented professionals have resulted in, what some authors have entitled ‘a war for talent’ (Michaels, Handfield-Jones, & Axelrod, 1997). Especially in the public sector, a sector that in the industrialized world has been confronted both with an aging work force as well as with a series of public management reforms (Pollitt, Van Thiel & Homburg, 2007), various scholars have analyzed (1) the motivations for people to join public sector organizations (cf. public service motivation literature, Steijn (2003)) and (2) retention and intention to leave organizations.

**Management and leadership quality**

With respect to determinants of nurse turnover in particular, various studies, (Flinkman, Leino-Kilpi, & Salanterä, 2010; Hayes, O’Brien-Pallas, Duffield, Shamian, Buchan, Hughes, Laschinger, North, & Stone, 2005; Parry, 2008; Price, 2004) have associated nurses’ intention to leave with components of nurse management, such as nurses’ (dis)satisfaction with their supervisors (Larrabee, 2003; Yin & Yang, 2002), social support by supervisors (Van der Heijden, Van Dam, & Hasselhorn, 2009) and supervisors’ leadership quality (Van der Heijden, Van Dam, & Hasselhorn, 2009). As such the conceptualization and operationalization of management and leadership heavily borrows from notions of perceived organizational support (see for instance Eisenberger, Huntington, Hutchison & Sowa, 1986)), and, more specifically, leader-member exchange (Wayne, Shore, Bommer & Tetrick, 2002). In the literature, perceived organizational support and leader-member exchange have been identified as being associated with employees’ morale and mood, which impacts on attitudes and behaviours that are associated with organizational commitment (Aselage &
Taken together, these studies suggest that nurses' satisfaction with management is negatively associated with their intention to leave.

H1: Satisfaction with management and leadership quality is negatively related to intention to leave.

*Pay and benefits*

A second cluster of determinants that can be identified in the literature comprises nurses' satisfaction with pay and benefits. Previous studies have shown that nurses' satisfaction with salary is negatively related to nurses' intention to leave (Gardulf, Söderström, Orton, Eriksson, Arnetz, & Nordström, 2005).

H2: Satisfaction with pay and benefits is negatively related to intention to leave.

*Job satisfaction*

Recently, authors have suggested that, generally, job satisfaction and work situation is likely to affect intention to leave (Chan, 2008; Ingersol Olsan, Drew-Cates, DeVinney, & Davis, 2002; Van der Heijden, Van Dam & Hasselhorn, 2009). In our study, job satisfaction refers to worker autonomy (Larrabee, 2003), appraisal, challenges encountered, and variety in tasks.

H3: Job satisfaction is negatively related to intention to leave.

*Work-home interference*

Work-home interference is also reported in the literature as an important determinant of nurses' consideration to leave their job (Van der Heijden, Van Dam, & Hasselhorn, 2009). Work-home interference is defined as a form of a role-conflict in which work and family pose different demands on a nurse. Based on findings by Van der Heijden, Van Dam & Hasselhorn (2009), we expect that work-home interference is positively associated with intention to leave.

H4: Work-home interference is positively related to intention to leave.

*Development opportunities*

Various authors have stipulated that another determinant of intention to leave could be the perceived possibilities for nurses to learn new skills, and their career development opportunities in general (Coomber & Barribal, 2007; Gardulf, Söderström, Orton, Eriksson, Arnetz, & Nordström, 2005).

H5: Perceived career development opportunities are negatively related to intention to leave.

*Methods and measurement*

*Procedure and Sample*
The data for the current study was gathered using an on-line questionnaire. The questionnaire was first pre-tested and discussed with various hospital stakeholders, such as departmental nurse managers and human resource managers. Subsequently, in May 2011, 675 nurses from various disciplines (see Table 2 for a list of involved departments) of a general Dutch hospital (Catherina Hospital Eindhoven, the Netherlands) were invited to fill out the questionnaire. The response rate was 47%, varying from 23.6% (general surgery) to 73.0% (orthopedics). Most nurses (91.8%) were female, and their mean age was 35.6 (males, SD = 12.1) and 36.5 (female, SD = 11.3). The vast majority of nurses were (general) registered nurses (55.7%), whereas 32.7% obtained a specialized qualification in for instance, pediatrics or geriatrics. In the sample, 3.1% of the respondents were assistant nurses1.

In order to assess the internal consistency of the scores, we used the Guttman Lambda six in stead of the arguably more widely used Cronbach’s alpha because the latter underestimates the reliability of scores and over estimates first factor saturation; Guttman’s Lambda six displays a better performance in these respects (Revelle, 1979). As a rule of thumb, 0.70 as a minimum score is used.

Measurement of intention to leave

In this article, we define intention to leave as an employee’s dissatisfaction with their job that may or may not urge the employee to change jobs. In quantitative research, intention to leave is often assessed using a single-item Likert scale (see Table 1 for an overview in this regard). Operationalizations in existing studies varied with respect to the use of a specific rating scale (levels of certainty of intention versus frequency of thinking about leaving), and with respect to the envisaged post-exit choice (see also Flinkman, Leino-Kilpi, & Salanterä, 2010).

Table 1: Existing operationalizations of intention to leave in quantitative studies (underlined elements indicate distinct features)

In the present study, it has been our aim to assess both the intention to leave as well as the post-exit choice. As the existing literature did not provide an existing operationalization of post-exit destinations (and post-exit destinations may be highly country- or region specific), we identified various possible post-exit destinations based on exploratory interviews with the hospital's human resource management staff and analyzed notes of exit interviews with nurses that had already left the hospital. Consequently, intention to leave was measured using a series of five items, asking for how often the respondents thought about leaving their current position and pursue a career: (1) in another department in the same institution (2) in another institution (3) in domiciled/community care (4) in a medical practitioner's office, and (5) as a self-employed nurse, each measured using a rating scale (1 = never to 4 = various times per week). For the eventual analysis, the scales were recoded into binary variables (0 = never, 1 = at least once a year).

Measurement of dissatisfaction with management and leadership quality

Dissatisfaction with management was measured using a twelve-item scale (main questions 18-21 in the questionnaire, see Appendix 1) with items taken from the international NEXT study survey, and more specifically, developed by Van der Heijden, Van Dam & Hasselhorn (2009) and by Kristensen (2000).

A sample item (translated-backtranslated from Dutch into English) was: “Is your manager in generally willing to help you with the performance of your tasks?”. Responses were made on a five-point rating scale. Consistency of the scale was assessed and resulted in satisfactory results (Guttman’s Lambda six = 0.84).

Measurement of satisfaction with pay and benefits

Dissatisfaction with pay and benefits was measured by means of 20 items (main questions 22-39) taken from Hasselhorn, Tackenberg, & Müller (2003). Responses were made on a five-item rating scale. A sample item (translated from Dutch into English) was: “How satisfied are you with your current salary in relation to other professions?” Guttman’s Lambda six for the scale was 0.85.

Measurement of job satisfaction

Job dissatisfaction was measured using 12 items adapted from Kristensen (2000) and Allen and Meyer (1990). A sample item (back-translated from Dutch into English) was: “I really feel that I belong in this healthcare institution”. Guttman’s Lambda six for this scale was 0.72.
Measurement of work-to-home interference

Work-to-home interference was measured using existing scales on work-family conflicts and family-work conflicts (Netemeyer, Boles, & McMurrian, 1996), resulting in a ten-item scale (question 41). Responses were made using five-point rating scales, with low scores indicating a higher amount of interference and high scores absence of interference. Guttman's Lambda six for this scale was 0.91.

Measurement of career development opportunities

Career development opportunities was assessed using a six-item rating scale, constructed based on Kristenson (2000). A sample item (translated from English into Dutch, and back-translated in English) was: “Do you feel that the work you do is important?” Guttman's Lambda six for this scale was 0.79.

Results

Preliminary analyses and model fit assumptions

In order to explain the dichotomous dependent variable (ITL), we used binary logistic regression analysis. In general, logistic regression models predict the probability of an event Y, (in this case, the probability of a nurse reporting his or her intention to leave) by means of independent variables that are binary, categorical or continuous (Pampel, 2000). Logistic regression requires the absence of multi-collinearity. Multi-collinearity was inspected using collinearity diagnostics, and since all tolerance statistics are above 0.1 and all VIF values are smaller than 10 – even smaller than 4, being a threshold value used by Garson (2009) – multi-collinearity is a non-issue in this data set.

Furthermore, the data were analyzed for auto-correlation using the Durbin-Watson (D-W) test. All D-W statistics resulted in scores above 1, indicating absence of auto-correlation.

Finally, measuring various (dependent and independent) variables in one questionnaire makes the analysis vulnerable to common method bias, defined as variance attributed to the measurement method rather than to the constructs the measures represent (Podsakoff, Mackenzie, Lee & Podsakoff, 2003). According to Podsakoff et al. (2003), common method bias may stem from ways in which items are presented to respondents, and (common) contexts or processes for measurement. Although common method bias can not be ruled out in studies were one questionnaire is used to assess various variables in a population of respondents, common method bias was both prevented on beforehand as well as checked statistically in the data analysis phase. The questionnaire was pre-tested in order to prevent ambiguities and unintended effects of question order, taking into account best-practice recommendations presented by Podsakoff et al (2003). Furthermore, as a statistical remedy, all variables in the study were loaded into an exploratory factor analysis (EFA) and the unrotated factor solution was inspected. The results of the unrotated factor analysis did not show a single factor, nor did a general factor emerge that accounted for the majority of the covariances among the measures (again
following the procedures proposed by Podsakoff et al (2003)). Consequently, it was concluded that common method bias was not likely to influence the outcomes of the analysis.

Descriptive findings

Table 2 lists the scores for the ITL scores for various post-exit choices. Looking at the percentages, moving to another department or to another hospital appear to be the most favorite post-exit choices, with domicile/community care and self-employed being the least favorite post-exit choices.

5 Nagelkerke $R^2 = 0.150$; the Hosmer and Lemeshow test of significance of the whole model resulted in a non-significant value (Chi-square = 9.245; d.f. = 8; $p = 0.322$), indicating that the model fits the data adequately.

6 Nagelkerke $R^2 = 0.132$; the Hosmer and Lemeshow test of significance of the whole model resulted in a non-significant value (Chi-square = 10.146; d.f. = 8; $p = 0.255$), indicating that the model fits the data adequately.

7 Nagelkerke $R^2 = 0.126$; the Hosmer and Lemeshow test of significance of the whole model resulted in a non-significant value (Chi-square = 4.908; d.f. = 8; $p = 0.767$), indicating that the model fits the data adequately.

8 Nagelkerke $R^2 = 0.058$; the Hosmer and Lemeshow test of significance of the whole model resulted in a non-significant value (Chi-square = 3.286; d.f. = 8; $p = 0.915$), indicating that the model fits the data adequately.
The issue of management and leadership skills, which is identified as one of the important determinants of job changes to other hospitals and to a general practitioner’s practice, is interesting to note from a more practical point of view,
as management and leadership skills may be more malleable in the short term than pay and benefits. After all, changes in salaries in the hospital under study are restricted by overarching agreements as agreed upon in negotiations between employer associations and trade unions. However, the issue of improving quality of nurse leadership by no means is a trivial exercise. Van der Heijden, Van Dam & Hasselhorn (2009) argued that nurses that are promoted to nurse managers are not always promoted based on their management skills and leadership abilities, but rather on the basis of their professional proficiency. Furthermore, it must be stressed that in the hospital under study, management had already acknowledged the need to develop management skills; however, management development programs were typically geared toward the needs of more senior management levels, and were not offered to nurse managers that are tasked with the day-to-day supervision and support of nurses actually delivering care at the shop floor of hospitals. Obviously, there are ample opportunities to improve this situation regarding management and supervisory skills.

Perhaps surprisingly, given the existing literature on nurses’ ITL, we did not find empirical support for an effect of (perceptions of) career development on either of the identified post-exit choices. Possibly, given the rather high mean score for this determinant (M = 4.10; S.D. = .51), nurses working in the participating hospital take their ample career opportunities for granted, herewith weakening its predictive power for intent to leave. Although we used existing measures both for satisfaction with pay and benefits on the one hand and career development on the other hand, perhaps respondents in the questionnaire expressed concerns over career development in terms of dissatisfaction with pay and benefits. Furthermore, perhaps career development issues are, more than other hypothesized determinants, highly situational. In that case, the specifics of the hospital under study (and, more specifically, possible more-than-average altruistic working ethics given the denomination of the hospital under study) may have played a role in the refutation of the career-development hypothesis in this study. However, further research is required to substantiate these issues more fully.

The findings reported in this article should be understood in the light of a number of limitations.

First, although the response rate was satisfactory and the sample size was sufficient to allow for the used regression techniques, the sample was taken from one hospital only. This implies that we cannot exclude the possibility that there are site-specific circumstances that may have affected and/or confounded our results. To say the least, generalization to nurses on other health care organizations should only be carried out with great care. However, in defense of the design to study nurse’s intentions to leave one specific hospital site, it must be stressed that the (institutional) context is constant, thus excluding a number of typical confounders such as plans for reorganization that may affect some hospitals but not other ones, variations in regional labor markets, et cetera, and therefore, generalization may be more valid than is apparent at first sight.
Second, using the survey, we assessed nurses’ self-reported intentions to leave, not the actual exit behavior of nurses. Turnover research (e.g. Adams & Beehr, 1998; Griffeth, Hom & Gaertner, 2000; Lee, Carswell & Allen, 2000) corroborates that turnover intention is a stronger predictor of actual turnover than other variables (Blau and Lunz, 1998). Furthermore, intention to leave the profession can be considered an indicator of people’s tendency to withdraw from a specific career situation (Hanisch and Hulin, 1990), and helps to overcome the fact that actual occupational turnover is a low base rate event. In addition, the intention to change one’s profession has been identified as an important outcome variable for its own sake (Blau & Lunz, 1998) since it represents the conscious decision component of change (Rhodes & Doering, 1993). For organizations, turnover intention is a more useful variable than actual turnover because it enables organizations to take action in order to retain employees for the organization. Still, future research is needed to establish the predictive validity of our research model for actual turnover.

Third, in line with much previous research, this study has emphasized the importance of management skills and leadership quality. However trivial this may seem, the adequacy of leadership and management activities may be highly situational, depending on site characteristics, the issues at hand, person-organization and person-task fit, et cetera. After all, if management skills and leadership quality are found to be crucial in preventing turnover of nurses in an ageing population with more challenging demands, we should deepen our understanding of the very concept of nurse leadership and typical nurse management skills, in order to eventually guarantee the quality of care that is delivered to patients now and in the future.

The abovementioned findings, interpretations and limitations can also be used to formulate an agenda for further research. A first direction for research activities is to study the careers of both nurses that have chosen to pursue a career in the same setting, as well as nurses that have chosen to change jobs, either within the same hospital, to extramural destinations, or even to other occupations. In doing so, it may be possible to analyze whether the determinants that can are supposed to affect nurse behavior actually change over time. Such a prospective design of course does not change the predictive nature of the determinants of the intention to leave, but rather may inform whether, seen from the point of view of the nurses under study, the determinants are (after-the-fact) credible reasons for changing jobs.

A second direction for research is to push for more methodological rigor in analyzing determinants of intention to leave by acknowledging a hierarchical structure in determinants. In most studies, as in this one, intention to leave is supposed to be determined by individual-level determinants, such as satisfaction with pay and benefits. However, it may be possible to hypothesize that there is a hierarchical structure in determinants of intention to leave. Some of the determinants may indeed be of an individual level, but other determinants may refer to an above-individual, group level, such as work atmosphere at a specific department, or to an organization level, such as hospital’s professional code of conduct, ethical principles adhered to, or general organizational strategy. A multilevel regression analysis of more elaborate data might be suitable to flesh
out the various levels of determinants, and in so doing, provide a more thorough and rigorous explanation of the intriguing phenomenon of nurse’s intention to leave.

Conclusion
This research has contributed to our understanding of nurses’ intention to leave (ITL). More specifically, the empirical evidence presented in this paper reveals key determinants of nurses’ intentions to leave to specific post-exit destinations, and, by doing so, contributes to a better understanding of the possible implications of perceived poor job satisfaction, poor pay and benefit satisfaction, less than optimal satisfaction with management and leadership, and work-to-home interference. As such, the paper provides empirical insights of why nurses display various reactions to work dissatisfaction, and adds empirical evidence to the 'ITL withdrawal process', that, until now has only scarcely been studied empirically.

By identifying key determinants of various ITL post-exit destinations, specific management concerns and issues for general hospital’s human resource management practices are identified, enabling both nurse managers as well as human resource managers to address the issue of nurse turnover and by doing so, improve quality of care and nursing outcomes.

Author contributions
LV and VH were responsible for the research conception and design. BvdH supplied important methodological content to the design of the study. Data was gathered and analyzed by LV. LV was responsible for the production of a thesis (supervised by VH) which was the basis for this article. VH was responsible for the drafting of this paper. LV and BvdH co-authored the paper, and made critical comments and revisions to the paper.

Funding
This research received no particular kind of funding from any public or private agency. The Catharina Hospital Eindhoven (the Netherlands) contributed to this research by offering an internship to LV as part of his Master program in Public Administration, and by supporting the data gathering process by non-monetary means.

Appendix A: Questionnaire

Part A: Questions about the healthcare institution you work in and about your personal situation.

1. What is your main work department?
   - Cardiology
   - Cardiothoracic surgery
   - Geriatrics
   - Neurology
   - Psychiatry
   - Shortstay and day care
   - Dialysis
   - Internal medicine
   - Lung
   - Oncology
   - Gynecology and obstetrics
   - In vitro fertilization
   - Pediatrics
   - Orthopedics

2. Do you always work in the same department?
   - 1 no, I move between departments a lot
   - 2 no, I occasionally move between departments
   - 3 yes, fixed department

3. What is your present position at work?
   - 1 sister/charge nurse
2 deputy sister/ deputy charge nurse
3 other nursing staff

4. How many nursing colleagues (including aids) do you usually work with?
I usually work
1 alone
2 with one colleague
3 with 2 to 4 colleagues
4 with 5 or more colleagues

5. How many patients do you work with during one shift?
approximately ____________ patients

6. Are there any vacant nursing posts in your work place at present?
1 no
2 yes
3 don’t know

7. Number of your work hours per week (on average):
a. according to work contract _____ hours per week
b. overtime: paid _____ hours per week
c. overtime: compensated by leave _____ hours per week
d. overtime: neither paid nor compensated by leave _____ hours per week
8. Do you have a permanent employment contract?
   1 yes
   2 no this ends: _____

9. What is your highest leaving certificate or diploma before nursing education?
   1 no leaving certificate
   2 GCSE or equivalent
   3 A levels
   4 NVQ

10. How many years did you study nursing? (in total)
    1 less than 1 year
    2 1 year
    3 2 years
    4 3 years
    5 4 years
    6 over 4 years

11. Which type of health care training do you have?
    1 no health care training
    2 nursing aid / assistant paediatric nurse
    3 qualified nurse
    4 specialist nurse
    5 assistant old people’s nurse
    6 old people’s nurse
    7 paediatric nurse
    8 midwife
9. other: ______________________________________

12. How many days did you participate in continuing professional development during the last 12 months?
   ___________ days

13. For how long have you worked in the nursing profession? (Please do not include your training)
    ___________ years

14. In how many different hospitals or other health care institutions have you worked so far?
    ___________ institutions

15. How long have you been working for your present employer?
    1 less than 6 months
    2 6 to 12 months
    3 1 – 2 years
    4 3 – 5 years
    5 more than 5 years

16. What is your age in years?
    ___________ years

17. Your gender:
    1 Male
    2 Female
Part B: Management

18. To what extent would you say that your immediate superior (e.g. ward sister)...
