#### Abstract

This study examined the cross-cultural generalizability of the theory of planned behavior (TPB) as applied to job seeking, by comparing samples of native-Dutch and Turkish individuals in The Netherlands. Results supported the equivalence of the measures used. Moreover, the TPB-relationships were found to be comparable across the two samples. Contrary to the predictions, intentions of Turkish individuals were not affected more by subjective norms and less by job search attitudes than those of native-Dutch individuals.

The cross-cultural generalizability of the theory of planned behavior: A study on job seeking in  
The Netherlands

The theory of planned behavior (TPB) is a widely used theoretical framework that details the determinants of human behavior (Ajzen, 1991). Meta-analysis demonstrated its validity in the prediction of a large variety of social behaviors (Armitage & Conner, 2001). Also in the context of job seeking, research has confirmed the validity of the TPB (e.g., Van Ryn & Vinokur, 1992). Studies on the TPB typically use Western samples, and job seeking has been studied almost exclusively from a Western point of view. Therefore the current study focused on the cross-cultural generalizability of the TPB in the context of job seeking.

Job seeking is an important aspect of people's work lives as it determines the opportunity set of potential jobs from which job seekers may choose, and influences employment outcomes such as job attainment and employment quality (Kanfer, Wanberg, & Kantrowitz, 2001). Although a considerable body of research has investigated the predictors of job seeking (see Kanfer et al., 2001), hardly any study investigated the generalizability of models explaining job search behavior to "non-traditional" applicant pools, such as ethnic minorities. The current study aims to fill this gap by examining the predictors of job seeking among Turkish immigrants in The Netherlands. These predictors were examined in the context of the TPB, and were compared with the predictors of job seeking in a representative sample of the native-Dutch population.

The Turkish migrant population was chosen because of its substantial size in The Netherlands, their relatively weak position at the labor market, and their cultural differences with the Dutch population. The first generation of Turkish immigrants came to The Netherlands in the late 60s and early 70s. As guest workers, they were mainly employed in lower skilled jobs, to resolve the shortages at the labor market for these jobs. Nowadays they are the largest ethnic minority group, with 2.1% of the total population. However, their position at the labor market is relatively weak, as is indicated by high unemployment rates and overrepresentation in lower skilled jobs. Turkish culture differs from Dutch culture in the level of individualism versus

collectivism (INDCOL). Whereas Dutch culture is a typical example of an individualistic culture, Turkish culture has been characterized as highly collectivistic (Hofstede, 1980; Javidan & House, 2001; Paşa, Kabasakal, & Bodur, 2001). The Turkish and Dutch cultures were selected because differences in INDCOL may affect the relationships as outlined by the TPB.

Applied to job seeking, the TPB states that the most proximal determinant of job search behavior is the individual's intention to engage in job seeking. Job search intention comprises the motivation necessary to engage in job seeking. The more an individual intends to engage in job seeking, the more likely it is that actual job search activities are performed (cf. Ajzen, 1991). Job search intention is predicted by the extent to which a person evaluates job seeking positively or negatively (i.e., job search attitude), by the individual's perception of social pressure to look for a (new) job (i.e., subjective norm), and by people's confidence in their ability to perform various job search activities (i.e., perceived behavioral control; Ajzen, 1991). That is, people who regard job seeking as more beneficial and more sensible will be more likely to intend to search for a (new) job than people with less positive attitudes towards job seeking. Also, individuals will be more likely to form job search intentions as they perceive more social pressure from important others to do so. Lastly, people will be more likely to make job search intentions if they are more confident about their ability to perform job search activities. Based on the TPB, we expected:

*Hypothesis 1:* (a) Job search attitude, (b) subjective norm, and (c) perceived behavioral control positively predict job search intention.

The TPB was hypothesized to be a valid framework to predict job seeking for both native-Dutch and Turkish-Dutch individuals. However, based on differences in INDCOL we expected differences in the relative weights of the predictors across the two cultural groups. In individualistic cultures people tend to perceive themselves as autonomous individuals who are independent of the group ('independent self'), and tend to prioritize personal goals over collective goals. Behavior in these cultures is guided more by personal attitudes than by social norms. Conversely, in collectivistic cultures people tend to perceive themselves as interdependent with

their group, and tend to prioritize goals of the in-group over their personal goals. Behavior is guided more by anticipated expectations of others or social norms of the in-group than by internal dispositions such as personality traits and personal attitudes (e.g., Markus & Kitayama, 1998). Applied to the TPB, these theories about INDCOL and the self suggest that in collectivistic cultures perceptions of social pressure (i.e., subjective norm) will predict behavior more strongly than in individualistic cultures. Internal dispositions such as personal attitudes are stronger predictors of behavior in individualistic cultures. Thus,

*Hypothesis 2:* Job search intentions of Turkish immigrants are (a) more strongly predicted by subjective norm, and (b) more weakly by job search attitude as compared to job search intentions of native-Dutch individuals.

## Method

### *Participants and procedures*

Two separate samples were used: one sample of Turkish immigrants, and one sample reflecting a cross-section of the native-Dutch population.

*Turkish sample.* Respondents of Turkish descent who resided in The Netherlands were recruited using a networking approach. Fifteen Turkish individuals distributed 1,156 questionnaires among relatives, friends, and acquaintances from Turkish descent that belong to the (potential) labor force (i.e., aged 15 to 65). Individuals who were willing to participate were given a questionnaire in Dutch or in Turkish, depending on their own preference. After completion, the questionnaires were recollected by the distributor. We used this approach because people are more likely to participate when someone they know personally asks them to. This way we were able to create a broad sample of individuals of Turkish descent living in The Netherlands, with a wide spread on variables such as gender, age, and level of education.

A total of 268 respondents participated (response rate of 23.2%). The majority of the respondents (68.3%) completed the Turkish version of the questionnaire. Almost two thirds of the respondents were male ( $n = 169$ ), age ranged from 16 to 48 ( $M = 27.0$ ,  $SD = 8.2$ ), 18.8% held a

college/university degree, and 70.1% of the respondents were employed. Almost 40% ( $n = 166$ ) were not born in The Netherlands. The average length of stay in The Netherlands of these foreign-born participants was 15.76 years ( $SD = 7.76$ ).

*Native-Dutch sample.* A total of 1,854 members (aged 15 to 65) of the telepanel of a Dutch research center (CentERdata) completed a questionnaire as part of a larger study (Van Hooft, Born, Taris, & Van der Flier, in press). This panel represents the Dutch population with regard to age, sex, religion, level of education, and geographical distribution. Participants with a nonnative-Dutch background were excluded from the analyses ( $n = 44$ ). About half of the respondents were male (52.3%), the average age was 40.2 ( $SD = 12.4$ ), 35.4% held a college/university degree, and 75.8% of the respondents were employed.

### *Measures*

Items were based on previous research (see Van Hooft et al., in press), translated into Turkish by two professional translators following a translation-back translation procedure, and pilot-tested among bilingual Turkish students.

*Dependent variable.* Job search intention was assessed by six items. Participants were asked to indicate how much time they intended to spend on job search activities (i.e., reading job ads, talking with friends/relatives about job leads, contacting employment agencies, looking for jobs on the internet, making inquiries to employers, and sending out application letters) in the next four months. Response options ranged from 1 = *no time at all* to 5 = *very much time*.

*Independent variables.* To measure *job search attitude* respondents were asked to indicate the extent to which they regarded it sensible, wise, and useless (reverse scored) to seek for a (new) job in the next four months. *Subjective norm* was measured with a 2-item scale, asking the respondents to indicate the extent to which their significant other respectively most people who are important to them think they should seek for a (new) job in the next four months. *Job search self-efficacy* was used as a measure of perceived behavioral control (Van Ryn & Vinokur, 1992; see also Ajzen, 1991). Six items were selected, including: "I have confidence in my abilities to

complete a good job-application” and “I am confident of my ability to make a good impression in job interviews”. Response options for all these items ranged from 1 = *strongly disagree* to 5 = *strongly agree*.

*Control variables.* Because the samples differed significantly regarding sex, age, level of education, and employment position, multivariate  $F(4, 2061) = 89.52, p < .001$ , these variables were selected as control variables. Sex was coded 0 = *male* and 1 = *female*. Level of education was coded 1 = *low* (i.e., primary education/lower vocational training), 2 = *medium* (i.e., secondary school/intermediate vocational training), 3 = *high* (i.e., college/university). Employment position was assessed with the following item: “Do you have a paid job at the moment?” (0 = *no*, 1 = *yes*).

### Analyses and results

Structural equation modeling using LISREL 8.30 was applied to examine the cross-cultural equivalence of our measures and to test the hypothesized structural model. Covariances between the items were analyzed (after listwise deletion), and maximum likelihood was used as the estimation method. Table 1 reports the goodness-of-fit statistics of the models tested, the resulting path coefficients, and the explained variance in intention.

First, the measurement model was tested in both samples separately using confirmatory factor analysis (CFA). Fit indices were satisfactory in both samples (e.g.,  $RMSEA < .06$ ,  $SRMR < .08$ ,  $CFI$  and  $NNFI$  close to .95; cf. Hu & Bentler, 1999), all factor loadings ( $\lambda_x$  and  $\lambda_y$ ) were high and significant, and modification indices were small. Because these analyses demonstrated that the observed variables were good indicators of the latent factors they were supposed to represent, we proceeded to testing the structural equation model (SEM) in each sample separately. The structural model with job search attitude, subjective norm, and self-efficacy predicting job search intention demonstrated satisfactory fit in both samples. However, only attitude significantly contributed to the prediction of intention in each sample, with path coefficients of .70 in the native-Dutch sample and .44 in the Turkish sample. Path coefficients of self-efficacy were comparable in magnitude across the samples, but due to differences in sample size significant in the native-Dutch sample

only. The effect of subjective norm was not significant in any of the two samples. Controlling for sex, age, level of education, and employment position hardly changed the results. Age had a small negative effect on intention in both samples. The effects of level of education and employment position were small and positive in both samples, but significant in the native-Dutch sample only.

Second, the generalizability of the measurement model and the invariance of the structural parameters across the samples were tested using multi-group analyses. A two-group CFA baseline model was estimated, in which all parameters were set free across the two groups. Next, a series of equality constraints were imposed, testing the degree of measurement equivalence. The baseline model showed adequate fit, supporting the generalizability of the factor pattern. Subsequent models with respectively the factor loadings, the factor variances, and the factor covariances set invariant, demonstrated only small decreases in model fit. As *CFI*- and *NNFI*-values decreased with .01 or less, the CFA-model was concluded to be equivalent across the two samples (cf. Cheung & Rensvold, 2002). Proceeding with the SEM-analyses, again a baseline model was estimated, in which all parameters were allowed to vary freely across the two groups. The baseline model fitted the data well. Subsequent models with equality constraints imposed on the factor loadings, path coefficients, and factor variances did not result in substantial deterioration of the model fit. The structural model was therefore concluded to be equivalent across the two groups. Inclusion of the control variables did not change these results.

### Discussion

The present study sought to examine the cross-cultural generalizability of the TPB as applied to job seeking, by comparing samples of native-Dutch and Turkish individuals in The Netherlands. Results supported the equivalence of the measures. Both the factor pattern and factor loadings were comparable across the two samples. Mixed support was found for the predictions based on the TPB. Whereas attitude had a strong effect on intention in both groups (Hypothesis 1a supported), the effect of subjective norm was not significant (Hypothesis 1b not supported). Self-efficacy had a small effect on intention that was significant in the native-Dutch group only

(Hypothesis 1c partially supported). Several explanations may be offered for the non-significant results for subjective norm. For example, job seeking may be of such importance to personal well-being that people are less likely to be heavily influenced by others in forming their intentions. However, a rerun of our analyses without the inclusion of the attitude items showed that subjective norm strongly related to intention in both groups, but did not add unique variance over and above the effect of attitude. This might suggest that attitude mediates the impact of subjective norm on intention.

Although the TPB was thus only partially supported, model invariance tests demonstrated that the structural relations as outlined by the TPB were comparable in the native-Dutch and the Turkish sample. Although the attitude-intention relation seemed to be stronger in the native-Dutch than in the Turkish group ( $\gamma = .71$  vs.  $\gamma = .40$ ), imposing an equality constraint on the attitude-intention and subjective norm-intention relations did not worsen model fit significantly. Thus, intentions in the Turkish sample did not seem to be more affected by subjective norms and less by personal attitudes than in the native-Dutch sample (Hypothesis 2 not supported). These findings conflict with other research on cultural differences in the context of job seeking, suggesting that subjective norm is a strong predictor of job search intention in collectivistic cultures (Van Hooft, Born, Taris, & Van der Flier, 2004). Although evidence exists that collectivistic values are likely to be transmitted within Turkish immigrant families (Phalet & Schönplflug, 2001), the Turkish individuals in our study might have adopted Dutch individualistic values with regard to job seeking.

Limitations of the present study include: non-random sampling of the Turkish group, sample size differences between the two groups, reliance on self-report measures, and focus on only two cultural groups. In conclusion, we found support for the cross-cultural generalizability of the TPB as applied to job seeking in The Netherlands. Future research, however, should examine whether this finding generalizes to other cultural groups and other types of behavior.
