Abstract

Background: Cardiovascular diseases (CVD) cause 1.8 million premature (<75 years) death annually in Europe. The majority of these deaths are preventable with the most efficient and cost-effective approach being on the population level. The aim of this position paper is to assist authorities in selecting the most adequate management strategies to prevent CVD.

Design and Methods: Experts reviewed and summarized the published evidence on the major modifiable CVD risk factors: food, physical inactivity, smoking, and alcohol. Population-based preventive strategies focus on fiscal measures (e.g. taxation), national and regional policies (e.g. smoke-free legislation), and environmental changes (e.g. availability of alcohol).

Results: Food is a complex area, but several strategies can be effective in increasing fruit and vegetables and lowering intake of salt, saturated fat, *trans*-fats, and free sugars. Tobacco and alcohol can be regulated mainly by fiscal measures and national policies, but local availability also plays a role. Changes in national policies and the built environment will integrate physical activity into daily life.

Conclusion: Societal changes and commercial influences have led to the present unhealthy environment, in which default option in life style increases CVD risk. A challenge for both central and local authorities is, therefore, to ensure healthier defaults. This position paper summarizes the evidence and recommends a number of structural strategies at international, national, and regional levels that in combination can substantially reduce CVD.

Introduction

This position paper summarizes the available evidence of the effect of population level changes on risk factors for cardiovascular diseases (CVD). Our aim is to assist national authorities in selecting the most adequate management strategy to prevent CVD. The recommendations address the established risk factors for CVD, and will be valid for some other non-communicable diseases sharing the same risk factors, particularly type 2 diabetes, lung diseases, and common cancers.¹ The evidence for changes in risk factors on a population level is based on best available scientific evidence. Recommendations for individual prevention approaches are given elsewhere.^{2,3}

The burden of CVD

CVD remain the main cause of death in Europe leading to more than 4.3 million deaths in 2005 – every second

death.⁴ Over 40% are premature, occurring before the age of 75 years (1.8 million), and 54% occur in women. Coronary heart disease (CHD) and stroke are the commonest forms of CVD constituting 22% (1.9 million) and 14% (1.2 million) of all deaths, respectively. CHD is responsible for 20% of all deaths before age 75.

CVD mortality rates have decreased steadily in the European Union (EU) since the 1980s, and in Central Europe since the 1990s.^{5,6} A worrying upward pattern seen in Commonwealth of Independent States (CIS) has recently changed into a decline, but still there is a huge variation in CVD mortality across Europe (Figure 1). Disability-adjusted life years (DALYs) provide an aggregate of years lost due to premature death and years of healthy life lost due to disability, and in 2005 CVD accounted for 34 million DALYs (23% of total).⁵ Age-adjusted DALYs in Eastern Europe were three times higher than in Southern Europe.

Figure 1. Age- and sex-adjusted mortality rates (per 100,000) from CVD in Europe in the years 1980–2009. The European region includes all European countries including the CIS countries. The CIS countries comprises: Armenia, Azerbaijan, Belarus, Kazakhstan, Kyrgyzstan, Republic of Moldova, Russian Federation, Turkmenistan, Tajikistan, Ukraine (still not an official member), and Uzbekistan. Source: World Health Organization.⁶

Unlike mortality trends, hospital discharge rates for CVD (acute coronary syndromes and stroke) have increased in the majority of European countries. Recently this has tended to stabilize in EU, but increased rampantly in CIS (Figure 2). CVD hospital discharge rates in Lithuania are fivefold higher than in Cyprus. Overall CHD hospital discharges are increasing in Europe due to the more recent EU member countries and CIS. Other forms of CVD (including heart failure) account for more than half of hospital discharges in the majority of European countries. The changing and diverse CVD patterns are in line with observed changes of life style factors dealt with in the present paper.⁷⁻¹⁰

In 2006, total CVD costs in EU exceeded 190 billion Euros, including 110 billion Euros for health care (54% to inpatient care, 28% to medications, and 18% other). This represents an average expenditure of 223 Euros per capita per annum or 10% of total health care

costs – ranging from 5% in Cyprus, Denmark, and Luxemburg to 17% in Poland.¹¹

Risk factors

Since the 1960s, multiple risk factors for CVD have been identified.^{2,5} Seven major modifiable risk factors – tobacco, high blood pressure, high cholesterol, alcohol, low fruit and vegetable intake, physical inactivity, high blood pressure, high cholesterol, and obesity – account for over 60% of total DALYs in Europe.⁵ As high cholesterol, blood pressure, and obesity are strictly linked to unhealthy diet and physical inactivity, the present position paper will focus on diet, smoking, physical inactivity, and alcohol, which all can be modified through population-based strategies.

Healthy diets are characterized by high intakes of fruits, vegetables, legumes, fibre, whole grains, nuts,

Figure 2. Age- and sex-adjusted hospital discharge rates (per 100,000) for CVD in Europe in the years 1980–2009. Source: World Health Organization.⁶

vegetable oils, and fish; whereas unhealthy diets are characterized by high intakes of salt, red meat, processed meat, saturated fat, *trans*-fat, refined grains, and refined sugars. Unhealthy diets greatly increase CVD incidence and premature mortality.³ Key problems are high salt intake,¹² sugar sweetened beverages, and saturated fat,^{13–15} each accounting for 10–15% of calories consumed by youth.¹⁶ Smoking and passive smoking are among the best-established risk factors for CVD and premature mortality.² Physical inactivity increases CVD and all-cause mortality.^{2,17} Recently even low-level physical activity has been shown beneficial for health,¹⁸ making ‘sedentarism’ (e.g. TV viewing, PC using) an independent risk factor.^{19,20} Both old and new media and systems of communication promote more sedentary habits and, frequently, imply higher consumption of snacks and junk food. Excess alcohol consumption is a risk factor for CVD.²¹ Light alcohol consumption may be protective;²² however, no controlled studies with sufficient long-term data exist,²³ and there are concerns about publication bias in studies analysing lower levels of intake (<50 g/day).²¹

Who is responsible? Prevention approaches and arenas

Rose made the seminal argument for a focus on population level strategies for disease prevention.²⁴ He identified that a small shift in the risk of disease across a whole population can lead to greater reductions in disease burden than a large shift among those persons already at high risk. Thus greater health benefits can be achieved if preventive efforts are focused on the whole populations rather than mainly on high-risk individuals. Traditional approaches to epidemiology and individual interventions have produced major advances in elucidating the relationship between risk factors and disease outcomes. However, efficacious treatments at an individual level may flounder when scaled up beyond individual intervention to population-level efforts directed to several thousands of individuals.²⁵

Socioecological theories have identified the relationships between different levels of determinants for chronic disease and consistently show that individual behaviour is nested within a number of other layers. CVD risk has, therefore, been variably depicted as the presence of lesions on an artery wall, blood levels of lipids, unhealthy diet and low physical activity, exposure to unhealthy food environments, dangerous neighbourhoods for active transport and urban planning, poverty, state and federal planning policy, and the implications of international trade agreements. These factors can be described as an axis of nested hierarchies from the micro level (e.g. individual choice, family influence) through the mezzo level (e.g. workplace,

health care) and macro level (e.g. policy at state, city, or regional level) to global level (e.g. national policies and implications of international trade).²⁶

While the personalized strategies will focus on the micro level, the population-based preventive strategies should focus on mezzo, macro, and global levels. Population-based strategies include fiscal measures (i.e. taxation and subsidies), international, national, and regional policy and legislation (e.g. smoke-free policies, rules for marketing, food production), and environmental changes. All strategies for changing risk factors, therefore, need to consider the interaction between levels and how policy change at national level shifts individual risk behaviour.^{27,28}

Several stakeholders at different levels are concerned for each of the factors addressed in this position paper:

- international level (WHO, WTO, EU)
- national level (government department, health authorities, health agencies, industries)
- regional level (relevant authorities, such as for traffic planning, schools, construction of public buildings).

Responsibility should be shared between politicians, administrative authorities, health professionals, and NGOs. They should scrutinize the balance between health and profit, and be aware of conflicts of interests with industries.²⁹ Communication to the general public should thus be the responsibility of health authorities, not industry.^{30,31} Mass media campaigns and individualized interventions to change behaviour can improve health, but are more likely to be effective if complementary policy or legal frameworks are in place making the healthy choices the easy choices.³² The diffusion of internet networks may obviously represent an opportunity.

Recommendations and actions

Food

Changing dietary patterns from unhealthy to healthy and lowering daily total energy intake will substantially lower cardiovascular risk.^{4,33,34} Diet is a very complex area in the cross field between personal choices, production, and marketing. Healthy food policies should aim to facilitate and incentivize positive interactions between governments, industry, and wider society to collaborate in achieving substantial reductions in CVD.

International level

WHO recommends salt intake to be less than 5 g/day, both saturated fat and free sugar to comprise less than 10% of total energy, and elimination of

industrially produced *trans*-fats (TFA).^{35,36} There is growing awareness of the potential benefits of policy intervention in the agricultural sector to influence agricultural production practice.³⁷ EU Common Agricultural Policy (CAP) and food systems have supported unhealthy diets. Future CAP reforms should, therefore, include public health nutrition in its objectives, e.g. by supporting a shift from meat and dairy products to fruit and vegetables.^{38–40}

National level

Pricing. Taxation of unhealthy food is estimated to reduce CVD death in UK by perhaps 2%.⁴¹ Taxation of sugar, fat, and salty foods are implemented in some countries.³⁴ In the USA, soda taxes are implemented in 14 states.¹⁴ No substantial knowledge of the effect on consumption or obesity exist,⁴² but tax is often lowered due to lobbying from industries.⁴³

Subsidies for fruit and vegetables increase affordability.⁴⁴ The EU school fruit scheme has been widely adopted, with some benefit.⁴⁵ Agricultural subsidies have been successful in Finland helping farmers to make substantial shifts from meat and dairy to oil, seed, and berry production.^{46,47}

Restriction/availability. Several countries have developed guidelines to reduce salt to below 6 g/day,¹² though relatively few have gone beyond policy statements.⁴⁸ Eighty percent of salt intake stems from the processed food industry¹² and increasing successes have followed pressure on food industry and governments.⁴⁹ Legislative measures were effective in reducing salt in Finland (from 14 to 9 g/day), and other countries have followed.⁵⁰ In contrast, voluntary agreements involving collaboration with food companies have achieved smaller reductions, e.g. UK (from 9.5 to 8.6 g/day).⁴ Modelling studies in USA,⁵¹ UK,⁵² and Australia⁵³ have consistently suggested that salt reduction is powerful and cost-saving. Legislation for salt reduction may be 20 times more effective than voluntary schemes.⁵³

Legislation to remove industrial *trans*-fatty acid (TFAs) has been successfully implemented in Denmark, Sweden, Iceland, Austria, Switzerland, Seattle, and New York.³⁶ Voluntary schemes are reducing TFA intakes more slowly in UK and Netherlands.^{4,36} Data on the effect on CVD are awaited.

Advertising of junk food (food high in fat, salt, and sugar). Restriction may be very efficient.^{54,55} In the UK, the Office of Communication (OFCOM) banned any TV advertising of food high in fat, salt, and sugar (HFSS) aimed at children, where they make up more than 60% of the audience.^{54,56} Exposure fell by about

one-third in 2007/08 compared to 2005. Data on actual changes in HFSS intake are needed.^{54,56}

Labelling. This aims to increase consumer information, inform consumer choice, and pressure manufacturers to reformulate. Traffic light schemes are consistently effective and preferred by consumers in diverse jurisdictions across Europe, USA, and Australia.^{57,58} The UK Food Standards Agency recommended traffic lights, but industry lobbying resulted in a more complex hybrid scheme. In the Netherlands, a 'Healthy choice logo' for recommended 'basic' products and 'Conscious choice logo' for non-basic products was introduced. The Nordic Council of Ministers has endorsed a keyhole symbol indicating healthy food items.⁵⁹ Additional data on the effect of labelling on changes in availability and in purchasing are needed.

Regional level

Restrictions/availability. Some countries have developed and promoted nutritional criteria for schools through government or local policies e.g. UK School Food Trust and Caroline Walker Trust.⁶⁰ Vending machines for confectionery and soft drinks were seen in less than 5% in primary schools in Denmark.⁶¹ Other countries are now banning such vending machines (France, UK, USA). Singapore regulated vending machines and gave access to water coolers resulting in decrease in obesity.⁶² It is important that schools avoid economic dependency on vending machines. HFSS food and snacks in schools also need control.⁴⁵ Controlling the number of fast food restaurants near schools appears potentially useful.⁶³ A borough in London (Barking and Dagenham) recently won a legal victory supporting a policy restricting takeaways near schools. Data on the effect of these regulations on HFSS intake among school children is needed.⁴⁴

Healthy food initiatives in public and workplace canteens were started in the North Karelia program then rolled out across Finland.⁶⁴ In 2008, Los Angeles banned new fast-food outlets to reduce obesity. The coverage of the ban was weak and there is uncertainty about any effect.⁶⁵

Smoking

Any reduction in smoking and second-hand smoke exposure will lead to reduced cardiovascular morbidity and mortality. Although smoking prevalence is declining, the decline is less evident in lower socioeconomic groups and underreporting is increasing.⁶⁶ There is no safe level of second-hand smoke exposure and a completely smoke-free environment is the only way to protect non-smokers. Voluntary policies, separate smoking

rooms, and improved ventilation do not reduce second-hand exposure to an acceptable level.^{67,68}

International level

The WHO Framework Convention on Tobacco Control (FCTC) has specified recommendations for the implementation of national, comprehensive smoke-free laws, currently adopted by more than 170 countries.⁶⁹ However, in several countries legislation offers only limited protection or laws are not enforced. To avoid border sales, harmonization of excise duties at a high level within the EU should be pursued.⁷⁰

National level

Pricing. For each 10% increase in retail prices, tobacco consumption is reduced by 4% in high-income and 8% in low- and middle-income countries. Teenagers and poor are more sensitive to increased taxation with 2–3-fold higher probability of quitting after price increases.^{71–73}

Restrictions. Adolescents do not worry about health consequences of smoking and are more susceptible to peer pressure and advertising. Several studies with community-level intervention have shown that restrictions on adolescents' access to tobacco leads to reduced smoking prevalence.^{74–76} Restriction on retail aimed at youth would include banning of tobacco vending machines. Restrictions on retail sale for adults, as implemented in some countries for alcohol, have not been studied. Smoking bans in the public domain led to reduction in exposure to passive smoking and an estimated 17% reduction in incidence of myocardial infarction,^{77,78} while it is less clear whether legislation also leads to smoking cessation in the general population.⁷⁹

Labeling. One of the best ways to raise awareness of the dangers of tobacco is through the adoption of large mandatory pictorial warnings on the pack. Although pictorial and text health warnings have been shown to increase perception of risk and to reduce smoking uptake, changes cannot be attributed to labelling alone.⁸⁰ Health warnings have greater impact in countries with more comprehensive tobacco control programmes and in smokers with lower socioeconomic status.⁸¹ To enhance effectiveness of pictorial warnings, they must be combined with plain, standardized packaging.^{70,82–86}

Advertising. Exposure to advertising is associated with increased likelihood that in particular adolescents will take up smoking.⁸⁷ A complete ban of all advertising and marketing may lead to 7% reduction in tobacco

consumption, whereas partial banning of advertising has little if any effect on smoking prevalence.⁸⁸

Media campaigns. TV campaigns may reduce smoking uptake by teenagers and increase quit rates among adults.^{89,90} Based on few and heterogeneous studies, a Cochrane review concluded that mass media campaigns may have an effect on smoking behaviour in adults,⁹¹ whereas anti-tobacco campaigns directed at youth in schools have not reduced initiation.^{92,93}

Regional level

Restriction. Smoking bans at workplaces have led to reductions in exposure to passive smoking, in particular among hospitality workers, decreased cigarette consumption during the working day, and higher smoking cessation rates.^{94,95} Restrictions on smoking in general may enhance a cultural shift towards 'denormalization' of smoking, as a high public support for and compliance with smoking bans has been seen after passing legislation.⁷⁹ Smoke-free policies at working sites can provide substantial saving to employers as well as health benefits for the former tobacco user⁹⁵ without harming business in restaurants and bars.^{96–98}

Physical inactivity

Any increase in daily physical activity and decrease in sedentary time will reduce CVD morbidity and mortality.^{18,99,100} Trends go towards integrating physical activity into daily life activities such as reducing sitting time⁹⁹ and promoting active commuting as cycling and walking to work. A simulation study showed that change in environment to support more active lifestyle was cost-effective.¹⁰¹ Public perception of the importance of physical activity is still relative low in some countries, e.g. Croatia.¹⁰²

Reviews^{103,104} and reports^{105–107} have summarized the available evidence on how to promote and create built or natural environments that encourage and support physical activity. A recent Cochrane review¹⁰⁸ concluded that there is a noticeable inconsistency of the findings of available studies and that there is a clear need for future well-designed intervention studies. The review mixes the effect of individualized intervention with mass campaigns and (seldom) structural changes, which makes it difficult to delimitate the effect of structural changes.

International level

Recommendations at population levels are to change environments that facilitate physical activities, which fit into daily routine making it easier for people to follow

the current guidelines, which includes moderate-intensity activities (e.g. brisk walking) for a minimum of 30 minutes on 5 days/week or vigorous-intensity activities (e.g. jogging) for a minimum of 25 minutes on 3 days/week, or a combination of both.¹⁰⁹

National and regional level

Pricing. Taxing private motor transport with introduction or road-user charges and higher parking fees together with cheaper public transport can support physically active modes of transport.¹⁰⁵

Restriction/availability. A re-allocation of road space by introducing cycle and footpath lanes, closing or narrowing roads in city, and creating or enhancing places for physical activity is beneficial.¹⁰³

Linkage of different sites (e.g. homes, schools) by appropriate walking and cycling networks (trail connectivity) including safe routes to schools will facilitate walking and cycling.^{105,107} Use of staircases rather than elevators and escalators can be encouraged as default by good visibility and signposting.¹¹⁰ Designing school playgrounds so that they encourage varied physically active play combined with it being compulsory to be in the schoolyard during lesson breaks will facilitate physical activity.¹¹¹

Encouragement of employees to walk, cycle, or use other modes of transport involving physical activity in travel to and from work and as part of their working day.¹⁰⁶ Finally, introduction of systematic breaks in sitting time is a promising new effort.^{99,106}

Alcohol

Although 'light-to-moderate' alcohol consumption may be beneficial in CVD prevention, the message is often interpreted inappropriately. Excessive alcohol intake is clearly associated with increased cardiovascular mortality²¹ and alcohol ranks as the second-leading cause of DALYs lost in high-income countries.¹¹² Recommending of alcohol consumption for non-drinking persons is therefore not supported.

International level

WHO and EU recommend taxation, low legal limits for alcohol concentrations in blood for drivers, minimum age for purchasing alcohol, and regulation of availability.^{30,113}

National level

Pricing. A huge literature establishes that for each 10% increase in retail price, alcohol consumption is

reduced by 5.1%, ranging from 4.6% for beer to 8.0% for spirits.¹¹⁴

Restriction. Age limits for sale and serving with consequences for shops and restaurant that violate the rules are effective.^{115–117} Various drink-driving strategies are very effective in reducing numbers of persons driving after drinking alcohol,^{118,119} which may have an indirect effect on the overall consumption of alcohol. Government retail monopolies for sale of alcohol can reduce alcohol-related harm due to restriction in the number of outlets for alcohol purchase; furthermore reducing the hours of sale of alcohol has shown beneficial effect.¹²⁰

Labelling. Labelling alcohol with information on caloric content and health warning messages of the harmful effects of alcohol has shown limited effect.¹²¹

Advertising. Alcohol advertising, promotion, and sponsorship of events is clearly related to initiation of young drinking, and it seems as if the effect of exposure is dose related and cumulative over time.¹¹⁶ This could support that banning alcohol advertising would be effective in reducing consumption.

Regional level. Alcohol regulations in policies on workplaces, educational centres, and schools are effective, whereas education of the harmful effect of alcohol in schools have no effect,¹¹⁶ which is the preferred recommendation of the alcohol industry.¹¹⁶

Discussion

Societal changes during the last decades have led to the present harmful environment with high calorie intake, low degree of physical activity, continuous smoking, and high alcohol intake. As systematic screening and multifactorial individualized intervention is insufficient in changing CVD risk at a population level,²⁵ a structural approach is called for. This paper shows several initiatives at international, national, and regional levels that can contribute to reduction in CVD.

Besides strategies including taxation, subsidies, and statutory regulation, strategies such as 'nudging' and 'default' have been proposed as tools.^{122,123} Nudge – to push mildly – can be done by setting the default to healthy. A default is an option that will be obtained if the chooser does nothing, so a large number of people will end up with that option, whether or not it is good for them. This is the way that advertising and space management in supermarkets work. Therefore, a task for both national and local authorities is to regulate society to the more healthy default. This was launched by WHO in 1986 – 'making the healthy choices the

Box. Population level changes to prevent CVD: main conclusions and recommendations

- CVD causes more than 4.3 million annual death in Europe and costs at least 190 billion €.
- Important modifiable risk factors for CVD (unhealthy diet, smoking, alcohol, and physical inactivity) all respond to structural changes in society.
- Population level interventions aim at small changes in the whole population, which can have a higher impact on overall CVD burden than changes among high-risk individuals.
- Responsibility for structural changes should be shared between politicians, administrative authorities, and health professionals. Changes should be at international, national, and local levels.
- Healthy dietary habits will be supported by changes in agricultural policies, tax on products with free sugar and saturated fat and subsidies for fruit and vegetables, reduction of salt and trans-fatty acids in processed foods, clear labelling of foods, and limiting advertising for junk food.
- Completely smoke-free environments are the only way to protect non-smokers. Smoking and second-hand smoking can be regulated by taxation, restrictions in sale and use, banning advertising, plain packaging, and warning labels.
- Physical activities should be integrated in daily life by subsidies to public transport and re-allocating of road space to cycle and footpath lanes. Changes in schools, worksites, and built environment can make physical activity a more natural part of daily life.
- Alcohol intake can be reduced by taxation, low availability, regulation of advertising, and low social and legal tolerance of drink driving.
- It is estimated that such population-level changes can halve CVD mortality rates.
- In a complex, modern society there is an interaction between personal choices, production and marketing. To secure a real free choice for citizens, health authorities need to ensure healthy defaults, thus balancing the vested interests of corporations, who are not responsible for public health.

easy choices'.¹²⁴ However, policies to promote healthy lifestyle routinely face opposition by commercial vested interest from corporations (e.g. food, tobacco, alcohol) and health authorities need to anticipate this conflict of interest in their attempt to change the CVD risk.^{29,31,125,126}

Opponents allege that the 'nanny state' hinders the free choice of people,^{122,127} but the fact is that people today are nudged in the wrong direction by corporations' de facto setting of the default option.¹²³ Yet, corporations do not have responsibility for population health – this is the responsibility of governments, which have a duty of care, already acknowledged in respect to public health successes including clean water and air, sanitation, and traffic regulation. For example, reducing air pollution is a prioritized area in Europe with the 6th Environment Action Programme^{128,129} based on the Clean Air for Europe programme¹³⁰ and the WHO guidelines for air quality.¹²⁸ The average exposure index (AEI) of PM_{2.5} in European countries (2007) varies from about 10 $\mu\text{g}/\text{m}^3$ in Ireland and Finland to above 30 $\mu\text{g}/\text{m}^3$ in Bulgaria and Romania.¹³¹ Estimates show that with a reduction in PM_{2.5} to 6 $\mu\text{g}/\text{m}^3$ mortality for cardiopulmonary diseases and lung cancer will be reduced by 17%.¹³² Changes from private cars to public transport and better facilities for physical active modes of transport will both increase physical activity and reduce pollution.

It is only natural to extend these well-established responsibilities to create healthy societies.¹²⁴ The freedom of choice will remain, so people still can make the unhealthy choices. But as most people want the healthy choice, a more healthy default will help in lowering the

CVD risk. New media, which can be used to promote unhealthy behaviours, could instead generate institutional strategies at national level to support healthier individual behaviours.¹³³

Social inequality in health is increasing¹³⁴ and is exacerbated by a predominant focus on individualized prevention.¹²² There is a concern about the impact of psychosocial factors including chronic stress and lack of social network influencing the burden of CVD, but the knowledge of which interventions are effective is sparse.¹³⁵ WHO recommends making social support in stress prevention an important goal for communities and managers.¹³⁶ The structural changes mentioned in this presentation seem to have the potential to decrease social inequality in health.¹²²

Population interventions tend to work quickly^{77,78} and to be cost saving.^{53,73,101} Structural changes to avoid chronic diseases are now favoured from several sides.¹³⁷ The growing literature of the possible impact of structural strategies on health signals a paradigm shift in CVD prevention. Small changes in the whole society – changes that will not be dramatic for the single citizen – will substantially change the risk of CVD according to Rose's preventive paradox.²⁴ A report from the National Institute of Clinical Excellence (NICE) have estimated that a UK national programme reducing population cardiovascular risk by 1% would prevent 25,000 CVD cases and generate savings of €40 million per annum. Reducing mean population cholesterol or blood pressure by 5% would result in annual savings exceeding €100 million.⁴ A WHO bulletin report suggests that CHD mortality rates easily could be halved by modest risk factor reduction¹³⁸ and that

improved diet alone could halve CVD death.³⁴ The question has been raised whether structural changes with a slight reduction over the whole spectre of CVD risk is more efficient than a high-risk strategy using, for example, the polypill (consisting of cholesterol-lowering, antihypertensive, and antiplatelet agents).^{139–142} Adapting the polypill approach includes screening with detection of high-risk persons, initiation of treatment and compliance, which will never reach 100%. And even if the 100% compliance was reached, it has been estimated that the population approach seems to be more effective.¹⁴³ The polypill should be reserved for people at high risk if its efficacy and safety is demonstrated. In general, population-based and high-risk strategies should be used complementarily.

Much research needs to be done, but the structural strategies represent a powerful and cost-effective strategy, which so far has been underestimated.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.
