Running title: CRP POCT in febrile children in general practice

Abstract

Background: Point-of-care testing for C-reactive protein (CRP) may be helpful in differentiating viral from bacterial infection. Such a device should give results comparable to laboratory testing. The aim was to evaluate two point-of-care CRP tests (Nycocard and QuikRead) in febrile children in general practice, compared to a reference immunoturbidimetric assay.

Methods: Cross-sectional study of febrile children aged 3 months to 6 years presented to a general practice out-of-hours service. Children were visited at home, where blood was taken for the tests, within 24 hours of presentation. The Nycocard test was performed at home, whereas the QuikRead and reference test were performed in the laboratory.

Results: 76 children were enrolled. All three CRP tests were performed in 59 children. The mean difference between the reference test and Nycocard and QuikRead was 0.6 mg/L and -6.1 mg/L, respectively. The slopes of the Passing and Bablok regression were 0.95 (95% CI 0.9-1.0) and 0.83 (95% CI 0.81-0.85) for Nycocard and QuikRead, respectively.

Conclusion: Up to a concentration of 160 mg/L the Nycocard correlated well with the reference test, while the QuikRead underestimated concentrations above 60 mg/L. The Nycocard test seems a good candidate for CRP point-of-care testing in general practice.

List of Abbreviations

SBI, serious bacterial infection; POCT, point-of-care testing; ICC, intraclass correlation coefficient

Introduction

Fever is very common among children in general practice (1). Febrile children are often presented in the evening, outside normal office hours and are therefore mostly seen in general practice out-of-hours services. Fever generally has no serious consequences, but approximately 1% of children develop a serious bacterial infection (SBI), e.g. pneumonia or meningitis, with possible life-threatening complications (2, 3). Early recognition and treatment of SBI leads to a better prognosis (4, 5). Differentiating the few bacterial infections from the bulk of self-limiting viral infections in febrile children is a great challenge for general practitioners.

The use of near-patient or point-of-care testing (POCT) for C-reactive protein (CRP) measurement in general practice has the advantage of providing the result within minutes, making early diagnosis and management of bacterial infections possible. Such POCT devices should give results comparable to reference testing and be feasible to use in daily practice.

CRP is the first described acute phase protein, produced by hepatocytes as part of the non-specific acute phase response to infection, inflammation and tissue damage (6). CRP values in healthy individuals are below 10 mg/L. After the onset of inflammation or tissue injury, CRP concentration increases rapidly in the first six hours, reaches maximal levels after approximately 48 hours and falls rapidly when stimulation ends. Therefore, CRP serves as a very useful marker in screening for infectious and inflammatory diseases as well as for monitoring the response to treatment or disease activity (6, 7).

The aim of this study was to evaluate two different POCT devices for CRP measurement, the Nycocard CRP and the QuikRead CRP, in febrile children presented to a general practice out-of-hours service.

Materials and methods

Patients

Febrile children, aged three months to six years, presented at a general practice out-of-hours service in Rotterdam on Monday to Thursday evenings were eligible for the study. Children were enrolled between March 7th and May 31st, 2005.

The receptionist of the service questioned the parents about the fever of the child. The parents were informed about the study and were visited at home by a research assistant within 24 hours. During the home visit, the parents answered a structured questionnaire and the child was physically examined following a structured scheme. A finger prick in the middle finger was performed according to the NCCLS protocol (8). The obtained capillary blood was immediately used to perform the Nycocard CRP test. Another 400 μL of blood was drawn in heparin microtainers. Subsequently, the tubes were centrifuged and plasma was stored at -20°C until measurement.

Parents gave written informed consent. Children resisting physical examination or the finger prick were not enrolled. The Dutch Central Committee on Research involving Human Subjects (CCMO) approved the study.

Primary outcome measure

The primary outcome measure was the difference between the CRP value measured by the reference test and the POCT CRP tests, in mg/L.

CRP tests

For the Nycocard CRP test (Clindia Diagnostics, Leusden, the Netherlands) 5 μL whole blood was taken to determine the CRP value in mg/L, using the Nycocard test kit. Two medical students performed all measurements. The medical students were trained by

highly qualified laboratory technicians of the department of clinical chemistry during five sessions before performing the Nycocard CRP test in children.

The QuikRead CRP test (Orion Corporation, Orion Diagnostica, Espoo, Finland) has been evaluated on the QuikRead System for both whole blood (20 μL) and plasma. In our evaluation protocol this CRP test was performed with plasma by trained laboratory technicians who were blinded for the results of the reference test, the Nycocard test and patient characteristics. 20 μL plasma was used to determine the CRP value in mg/L.

For the reference CRP test, the Tina-quant CRP Hitachi 912 (Roche Diagnostics, Penzberg, Germany) was used, which has been standardized against the CRM 470 (9). All plasma samples were analyzed in one batch after the enrollment period and laboratory technicians were blinded for the POCT CRP results.

Patient characteristics

Since the medical students were not blinded for patient characteristics, the Nycocard CRP results may be influenced by characteristics of the children such as gender, height of the fever, duration of fever at the moment of the CRP measurement, and an “illness score”. This latter score is a measure of the first impression of the general condition or illness of the child. It is categorized into not ill, slightly ill, moderately ill and seriously ill. These characteristics were assessed during the home visit.

Statistical analysis

The linear association between the results given by the POCT CRP tests and the reference test was analyzed using Pearson’s correlation coefficient. The agreement between the results was analyzed with the intraclass correlation coefficient (ICC). The ICC produces measures of agreement of values within cases and ranges from 0 to 1. An ICC of 0.8 is accepted as a good agreement (10).

The differences between the POCT CRP tests and the reference test were analyzed using the Bland and Altman method (11) and the Passing and Bablok regression (12). We considered the POCT CRP test clinically valid when results did not deviate more than 10 mg/L from the results of the reference test in the concentration range of 0-70 mg/L.

The non-parametrical Mann-Whitney test was used to test the relationship of the patient characteristics gender, body temperature, duration of fever and illness score, with the difference between the POCT CRP tests and the reference test. Body temperature was dichotomized at 38°C, duration of fever at 24 hours, and illness score at not ill versus ill (slightly, moderately and seriously ill).

Assuming an ICC of 0.9 a minimum of 46 individuals had to be included to reject the null hypothesis of ICC 0.8 with $\alpha = 0.05$ and a power of 80%.

Results

During the enrollment period 76 children were visited. In 15 children CRP values could not be measured by the reference test due to insufficient material. Main reasons for insufficient material were no consent for the finger prick and resistance of the child. The results of 61 and 59 children were analyzed for Nycocard CRP and QuikRead CRP measurement, respectively. Rectal temperature could not be measured in two children and temperature was measured axillary in another child.

Characteristics of the 76 enrolled children are presented in Table 1. The median age was 21 months (ranging from 3 to 71 months). The 61 children with full CRP data tended to be older, more often male and to have a longer duration of fever. The median height of the fever in these 61 children was 37.7°C (ranging from 34.8 to 39.9°C) and did not differ from the children lacking reference CRP data.

TABLE 1

Agreement

The correlation coefficients of both CRP tests with the reference test were 0.99. The overall ICC value as well as the ICC value in the concentration range of 0-70 mg/L was 0.99 for Nycocard, whereas both ICC values were 0.98 for QuikRead.

Bland and Altman analysis

The overall mean difference between the Nycocard CRP test and the reference test was 0.6 mg/L (n=61; 2 SD 19.7). In the concentration range of 0-70 mg/L the mean difference was 1.4 mg/L (n=46; 2 SD 11) and in the concentrations above 70 mg/L the mean difference was -1.9 mg/L (n=15; 2 SD 35.4). The overall mean difference between

the QuikRead test and the reference test was -6.1 mg/L ($n=59$; 2 SD 31.3). In the concentration range 0-70 mg/L the mean difference was -0.4 mg/L ($n=46$; 2 SD 11.8) and in the concentrations above 70 mg/L the mean difference was -26.4 mg/L ($n=13$; 2 SD 44). The Bland and Altman plots are presented in Figure 1.

Of the Nycocard results, 89% fell within -10 mg/L or +10 mg/L of the reference test results. In the concentration range of 0-70 mg/L, the maximum difference was exceeded in 2 out of 46 results (4.3%), by 14 and 24 mg/L. Of the QuikRead results, 78% fell within -10 mg/L or +10 mg/L of the reference test results. In the concentration range of 0-70 mg/L, the maximum difference was exceeded in 2 out of 46 results (4.3%), by -15 and -28 mg/L.

FIGURE 1

Passing and Bablok analysis

The intercept of the Nycocard and reference test comparison was 2.3 (95% CI 1.0-3.4) with a slope of 0.95 (95% CI 0.9-1.0). The cusum test p-value was between 0.01 and 0.05. In the QuikRead and reference test comparison the intercept was 3.9 (95% CI 3.3-4.6) with a slope of 0.83 (95% CI 0.81-0.85). The cusum test p-value was ≥ 0.1 . The plots are presented in Figure 2.

FIGURE 2

Patient characteristics

None of the patient characteristics gender, duration and height of fever and illness score was related to the differences between the reference test and the Nycocard test (p-values 0.23-0.73). The distribution of CRP values for each of the three tests in the illness score categories not ill, slightly ill and ill (six moderately ill and one seriously ill) is presented in Figure 3.

FIGURE 3

Discussion

In this study two CRP POCT devices for clinical use in febrile children in general practice were compared to a routinely used laboratory method. Overall the Nycocard CRP test correlated well with the reference test, while the QuikRead CRP test underestimated the reference test above the concentration of 60 mg/L.

The Bland and Altman plot of the Nycocard test shows a good correlation with the reference test up to a CRP concentration of 160 mg/L with only three outliers, but a substantial increase in distribution with deviations of more than 10 mg/L above a concentration of around 200 mg/L. The plot of the QuikRead test shows a smaller distribution up to a concentration of 60 mg/L compared to the Nycocard, but an increasing distribution above 40 mg/L with deviations of more than 10 mg/L above 60 mg/L. Furthermore, the Passing & Bablok comparison shows a small constant bias in both tests, with a larger distribution in the lower concentration range for the Nycocard. However, the slope of the regression line of QuikRead indicates a proportional bias as well, indicating that the QuikRead deviation from the reference test increases with increasing CRP values, whereas the Nycocard deviation from the reference test is not dependent on the CRP values (up to 160 mg/L).

Both tests show less precise measurement of CRP values in the higher concentration range. Most uncertainty in distinguishing viral from bacterial infection exists between CRP concentrations of 10 and 70 mg/L (13-15). A deviance in CRP concentration of 10 mg/L of the reference test in this clinically relevant range may change the management of the febrile child (16), therefore the POCT device needs to correlate well in this concentration range. In the clinically relevant range the maximum difference was exceeded in only 4.3% in both tests.

The Nycocard test produced higher values than the reference test, overall as well as in the case of outliers in the concentration range of 0-70 mg/L. The QuikRead, however, produced increasingly lower values than the reference test above 40 mg/L, which is in the clinically relevant range. Possible consequences of this imprecision in daily practice may be more unnecessary prescription of antibiotics and more hospital referral using the Nycocard, or missing children with bacterial infection using the QuikRead test. Randomized controlled trials are needed to evaluate the possible consequences.

Medical students performed the Nycocard test during home visits in general practice, whereas experienced personnel in the laboratory performed the QuikRead test. This could explain the larger distribution with Nycocard in the 0-70 mg/L range and this might indicate that QuikRead would perform less in daily practice. However, overall the QuikRead test would be expected to perform better in the laboratory by trained technicians compared to the Nycocard test performed at home.

The Nycocard CRP test can be carried out within 5 minutes using only 5 μL whole blood, whereas the QuikRead test requires first a dilution of 20 μL whole blood with 1 mL of buffer after which a blank measurement is needed. Although we did not evaluate the use of the QuikRead System at home, the use of Nycocard at home seems to be more feasible because fewer actions are needed.

The patient characteristics height and duration of fever, gender and ill score were not related to the difference between the Nycocard CRP value and the reference CRP value. Thus, when CRP measurement is performed on a POCT device by a general practitioner or assistant these variables do not seem to influence the results.

Our results were in accordance with the results of other studies with the Nycocard device. Most studies concluded that use of the Nycocard was acceptable for POCT (17-

19). Our results for QuikRead were different from previous studies. We are aware of two studies evaluating QuikRead, one in general practice (20) and one in the emergency room setting (21). Seamark et al. tested the device in patients referred with a variety of conditions and found a mean difference of 1 mg/L, with 95% of the POCT results within ± 10 mg/L of the mean value; the age of the patients is not given. Esposito et al. concluded that QuikRead and the standard reference assay showed similar median CRP levels and similar distribution of values. Both studies concluded that QuikRead performed reliably compared to a reference method. Taking into account the increasing underestimation of CRP values above 60 mg/L and the more labor-intensive method, we feel that, although not tested in daily practice, QuikRead is less suitable for CRP testing in general practice or an emergency room setting and more suitable for the laboratory setting.

The use of CRP as a diagnostic marker for SBI has been studied and debated extensively. Several studies indicate that an increased CRP concentration is related to a higher risk of SBI in febrile children (14-16, 22). However, the management of febrile children by the general practitioner should not be based only on a CRP value, but also on other grounds e.g. clinical presentation, duration of symptoms and medical history. Our results show that the elevation of CRP concentration tends to be higher and the distribution of CRP values to be more widespread among febrile children who appear ill compared to children who appear well. In order to determine the effect of CRP POCT on clinical decision-making, further large prospective studies are needed (23). In addition, high quality diagnostic studies are needed to clarify the added diagnostic value of CRP along with other variables in differentiating bacterial from viral infections.

The use of POC CRP tests in general practice for early diagnosis and management of febrile children is promising. We feel that the Nycocard CRP test is a good candidate to meet this purpose.

Acknowledgements

We greatly appreciate the contribution of the research assistants, the laboratory technicians of the Sophia Children's Hospital, and the general practice out-of-hours service Rotterdam-South.

Clindia Benelux BV, Leusden, The Netherlands and Mediphos Medical Supplies BV, Renkum, The Netherlands, provided CRP testing devices.

ZonMw (Dutch Organization for Health Research and Development), Programme Common Diseases funded this study.
